A variety of game was once abundant, but this is now sadly depleted because of overhunting and habitat destruction. One animal of note is the pangolin, a superficially anteater-like creature with hair matted into hard scales. It is believed to be powerfully nourishing and is eaten as medicine rather than as a delicacy. A recipe from Gueizhou involves cooking it with almost every strong-flavored ingredient in the Chinese repertoire, suggesting that there is a need to kill the flavor of the animal. The pangolin appears to have no scientifically verifiable healing qualities, and is probably regarded as medicinal because of its strange appearance, which suggests powerful *qi* (spirit or energy).

The piquant spicing is an old tradition. The chile pepper now dominates, making this by far the spiciest cuisine in China. Chile entered from the New World in fairly recent times, probably overland from India and/or upriver from Macau and east China in the seventeenth century. However, the area relished piquancy before this. The *Songs of the South*, a compilation of poetry from the old state of Chu, mentions the use of smartweed, southernwood, and other pungent herbs and spices. Ginger and garlic were always commonly used. Dried daylily buds, also peppery in the mouth, have also been used since time immemorial. Also ancient in importance is *huajiao*, known in English as “Sichuan pepper,” “brown

pepper,” or “fagara,” and scientifically as *Zanthoxylum* spp. This plant is a sprawling shrub or small tree. Being thorny, it is sometimes used as a living fence that has the side benefit of producing useful fruit. The latter is a small brown berry. The berries grow twinned on a short stem, and provided an ancient poetic euphemism for the male genitalia. They have a pungent, rich taste with overtones of citrus as well as pepperiness, and they produce a peculiar numb feeling in the mouth when chewed.

At some point in ancient historic time, true pepper began to be traded into China from southeast Asia. It was enthusiastically accepted in west China. As elsewhere in China, pepper is used almost exclusively in the white form, made from immature fruits with the dark coat rubbed off, as opposed to the black form (entire mature fruits) used in most of the world.

Thus, west Chinese cooking was spicy long before chilies came, and preadapted it to the latter. Today, Hunan-Sichuan cuisine is the only one in the world that makes heavy use of all three types of pepper—brown, white, and red—and routinely uses all three in the same dishes. Chinese, like English, classes all as “peppers” (*jiau* is the Chinese equivalent, and originally referred to brown pepper); they are botanically unrelated. Only black (and white) pepper is in the pepper family (Piperaceae); brown pepper is in the citrus family (Rutaceae), while chilies are in the Solanaceae along with tomatoes and white potatoes.

A full meal normally consists of a starch staple, usually rice, with steamed and/or stir-fried dishes as topping, and an accompanying soup. Minor meals (breakfasts, light lunches) or snacks involve dumplings or noodle soups. Chilies, brown pepper, and other hot spices are found primarily in the stir-fried dishes and the soups.

Several Sichuan dishes have become widely known. Duck smoked over smoldering tea leaves and camphor chips is the most elegant of these. It is smoked briefly in the cooking process, not smoke-cured for long storage. More common is hot and sour soup (*suan la tang*), which traditionally involves dried daylily buds, montane fungi, slivered bamboo shoots, coagulated chicken or duck blood and/or meat, sesame oil, white grain vinegar, chilies, white pepper, and sometimes other ingredients. It is a flexible recipe, varying greatly according to taste and circumstance.

Chicken is often cut into small cubes and stir-fried with chilies and various vegetables. A variant of this with peanuts (from the New World) and (usually) dried tangerine peel is Gung Bao chicken, named for a military officer said to have invented (or relished) it. A range of “fish flavored” dishes, especially eggplant, are named not because they taste like fish but because they are flavored as fish are: that is, with garlic, ginger, scallions, oil, and often Chinese “wine.”

Particularly characteristic are stir-fried dishes of bean curd with garlic, brown pepper, and chilies. The

Woman selling steamed dumplings from a street stall in Sichuan province. © NIK WHEELER/CORBIS.

most famous of these today is *ma po dou fu*, literally “hemp woman’s bean curd,” which consists of small cubes of bean curd stir-fried in sesame oil with garlic, brown pepper, chilies, and fermented broad bean–chile paste; ground or finely chopped pork is often added, as is white pepper. As usual, countless variants of this dish exist, involving such items as mushrooms or fungi. Some are quite mild, but true Sichuan versions can be literally blistering. Also countless are the theories about the name; the most believable is that the dish was invented by women of the Ma (“hemp”) family.

Hunan’s cuisine has the same basic flavor mix as Sichuan’s, but uses more fish and chicken. Finely chopped pork, flavored and then steamed in a bamboo tube, is a distinctive dish. Yunnan cuisine is simpler. The distinctive Yunnan ham enters into almost everything. Being expensive and strong-flavored, it is used more as a spice than as a main ingredient; small amounts of chopped ham are added to dishes. Most common, and spectacular, is a dish in which oil is heated in a pan until it actually catches fire; then cooked lima beans, garlic, chilies, and ham bits are thrown into the flaming oil and quickly seared. Noodle dishes are abundant. Often the noodles are only partially cooked, then at the table they are slid into soup that is served at the boiling point; the noodles finish cooking in the soup while the diner waits. This is known as “across-the-bridge noodles.”

Drinks include some of China’s best tea, raised in the mountains of the area. Yunnan in particular is famous for tea. The plant originated nearby, in the area where Tibet, Burma, and India come together. Spreading to metropolitan China at some uncertain point in early historic times, it became popular during the Tang dynasty, being seen as an exotic southwestern luxury at that time. Only during Sung did it become widely important as an everyday (if expensive) drink. Other herbal teas and drinks are common and are used for a range of ills.

Alcoholic drinks run the usual gamut of grain-based “wines” and distilled liquors. Gueizhou is famous for its *maotai*, powerful clear liquor traditionally distilled from millet. Most of the minority groups brew distinctive “wines” or beers from rice or other grains. Drinking these local products is important on festive occasions, including the widespread spring festivals at which groups of adolescent boys sing courting songs to groups of girls, who answer in kind.

Today, west China supports an enormous food industry. Yunnan hams and teas, Sichuan pickles, Gueizhou *maotai*, and Hunan hot bean pastes are world famous. Sichuan-style restaurants are found in major cities around the globe, and classic Sichuan dishes are found in virtually every eclectic Chinese restaurant.

### ZHEJIANG (CHEKIANG) CUISINE

Zhejiang Province includes the core of the vast Yangzi delta region, China's richest, most highly educated, and most progressive region throughout much of history. Its great cities of Shanghai (now a separate metropolitan area), Suzhou, Hangzhou, and Ningbo form an arc around the Yangzi mouth. Each of these cities has its own culinary specialties.

Shanghai has grown very recently to prominence as a city; it is basically a product of imperialism, having been developed as a port by the English in the nineteenth century. It has its own variant of Eastern foodways, based on local traditions but adding influences from all up and down the Yangzi valley.

Zhejiang is also the core of the ancient state of Wu, which may have been largely non-Chinese-speaking, and which certainly maintained a sophisticated and elaborate culture rather different from that of the Central Plain to the northwest. The name “Wu” is still used for the region, and for the language spoken there—a language usually miscalled a “dialect,” but as separate from Putonghua as French is from Spanish.

Zhejiang cuisine is the most elaborate form of a culinary style more broadly called “eastern,” and found throughout the old state of Wu and its bordering areas. Besides Zhejiang, the provinces involved are Jiangsu, Anhui, and at least part of Jiangxi. Fujian province (ancient Min) is linguistically and culturally a very different entity, but its cuisines fall into a broadly eastern pattern, blending southward into more Cantonese-oriented foodways.

Agriculture in the region is as intensive as any in the world. Multiple cropping, heavy fertilizer use, systematic intercropping, and special production systems allow farms as small as an American suburban lot to produce a (bare) living. One common system, described by writers such as F. H. King, Fei Hsiao-Tung, and Philip Huang, involved producing rice and silk; mulberries grew along the dikes between the ricefields, holding the soil while producing leaves for silkworms. The mountains that ring the delta country are usually too steep for grain farming, but they are ideal for tea. This tea region, which includes much of Fujian and leaps the narrow strait to include northern Taiwan, produces what is generally regarded as the best in the world. Green (unfermented) and oolong (slightly fermented) teas dominate, as opposed to black (fermented) teas, which are notably less important. An extreme connoisseurship of tea exists in the area. Gourmets once not only discriminated teas from particular mountains and estates, but saved snow water for tea, or went to great lengths to obtain water from special wells and springs.

The markets of Zhejiang have always been famous for their size and the variety of offerings.

The staple foods in Zhejiang, and in most of the Yangzi region, are rice and wheat. The former can be grown in the summer, the latter in winter. Both were, and are, about equally important in the daily diet. Fox-tail millet was once common, but has been recently replaced by maize. Soybeans can be produced, but flourish better in more northern climes. A vast range of vegetables and fruits is produced. Specialty fruits include giant pears, mentioned by many authors, including Marco Polo. These can weigh several pounds apiece. Among the vegetables are specialized gourmet varieties of Chinese cabbage and snowpeas. The tender tips of the peavines are preferred to the pods and seeds, and are, in fact, often the most expensive items in a market. They are considered the ultimate in refinement because of their delicate taste and their *cui* texture. This quintessentially Chinese term is the highest praise for vegetables; it refers to foods that offer initial resistance to a bite, then suddenly give way and are succulent and moist. (Usually translated “crisp,” it refers to the crispness of a ripe apple, not that of a potato crisp.) Peavines are now appearing in the United States, and one can obtain seeds of the varieties in question.

Pigs, chickens, and ducks abound; sheep and cattle are uncommon and rarely eaten. The most important source of animal protein, however, is the water. Zhejiang is as amphibious as the Netherlands, with fresh and salt water interpenetrating and interdigitating in complex patterns. No one is far from water.

When the state of Wu flourished, the river carried incredible quantities of nutrients. Currents and tides brought still more nutrient from the seaward side. The result was a high-energy, high-nutrient environment, one of the most biotically productive on earth. Vast schools of fishes migrated up the river or along the coast. Alligators, river dolphins, and turtles of many species abounded. Huge beds of shellfish existed. The land was rich in game of all sorts. Today, this bounty is virtually gone. The Yangzi flow is reduced and terribly polluted. Overhunting, overfishing, pollution, and land reclamation have destroyed almost all the game and large water animals, and most of the fish stocks.

Even now, however, the delta region is relatively rich in seafood. Fish, crabs, shrimps, and shellfish remain common. Overfishing of wild stocks has been compensated by a huge expansion of aquaculture. Practiced since ancient times, fish farming now supplies most of the fish in China, and is concentrated in the Yangzi basin.

Wu's dependence on water foods was a source of merriment in earlier times. Northern and especially northwestern Chinese, from drier and more grazing-oriented lands, laughed at the "southern" taste for frogs and snails much as English used to laugh at French for eating the same. The citizens of Wu replied in kind, ridiculing the rank mutton and "barbaric" yogurt of the northwest. Françoise Sabban notes that, as early as the third century, Zhang Hua could write: "The people of the South and the East eat seafoods while the people of the North and West delight in hares, rats and other game and are not aware of their gamey smell" (p. 2). Such comments were barbed because the north usually had the political power while the southeast usually had the wealth; mutual envy sharpened tongues.

The other distinctive qualities of Zhejiang food are a proclivity for sweet and unctuous flavors; a rich quality, with much oil and thick sauces; and a devotion to extreme freshness. The sweet taste seems to be ancient; in the classic fivefold division of the cosmos, typical of Chinese thought since the early Han dynasty, the flavor associated with the east is sweetness. This obviously is not mere cosmological speculation, but a recognition of reality. (The west is associated with pungency, as is true of its cuisine to this day. The north is salt, south bitter, east sour, and center sweet.)

The freshness is also a result of landscape; preserving food is not easy in the hot, wet climate, and is unnecessary because of the twelve-month growing and fishing season. However, some interesting ferments are prepared, and China's best vinegar, the aged vinegar of

Chinese wolfberries or boxthorn (*Lycium chinense*) are known as *gau gei choi* in Chinese. They originate in the hot western regions of China and are used extensively in cookery and in botanical medicines. The leaves are used for herbal tea. PHOTO L. WILBUR ZIMMERMAN. ROUGHWOOD SEED COLLECTION.

Zhenjiang, comes from Jiangsu. This vinegar occupies the place in Chinese cuisine that balsamic does in Italian, and, in fact, it is vaguely reminiscent of balsamic in appearance. In Fujian, a brilliant purple-red fungal ferment is cultivated, and applied to almost anything and everything. Noteworthy is a dish of raw crab marinated in this ferment along with grain "wine," vinegar, and other flavorings. It is an acquired taste.

Those affluent enough ate three meals a day and snacks as well. The basic main-meal pattern is rice with one to three dishes for topping. Wheat appears as the basis of minor meals and snacks: filled dumplings, noodle soups, and various cakes. Sticky rice is made into cakes and noodles as well. The hot and amphibious landscape makes soup an attractive option. (China's—if not the world's—center of soup-eating is just southward, in Fujian, where it is perfectly routine to serve three or four different soups among the main courses in a twelve-course banquet, and Simoons reports a banquet at which "seven out of ten dishes were soups" [p. 50]). Ginger, green onions, garlic, local "wine," sugar, and vinegar are common flavorings. Less use is made of spices and bean pastes than in the west and south of China.

Among the major uses for the aquatic bounty are fish in sweet-sour or rich brown sauces, West Lake fish (from the West Lake at Hangzhou), braised eels, softshell crabs, crabs with roe in breeding season, countless shrimp dishes, stir-fried frogs' legs, and many snail and clam dishes. Even the tiniest shellfish are eaten. Among dishes drawing on the land, beggar's chicken is perhaps the most interesting; it is associated with the Shanghai area. A whole chicken is stuffed with fragrant leaves, buds, and spices, wrapped in still more leaves, encased in clay, and baked in a fire. The clay is broken (today, often, with an unromantic soft drink bottle) and the chicken served.

Like similar preparations around the world, this dish is said to originate among thieves who had to hide their stolen fowl.

Zhejiang was once a center of Buddhism, including Zen, and thus a great vegetarian cuisine developed. Based largely on soybean and wheat gluten preparations, it sometimes extends to include oysters and similarly sedentary shellfish, which do not seem alive. Imitation meats are prepared from bean curd skin and wheat gluten; they are convincing to the degree that their flavors are disguised by thick sauces.

At the other end of the puritanism scale is a dish centered on northern Fujian, “Buddha Jumped over the Wall”; it consists of long-simmered innards and tough cuts of meat. It smells so wonderful as it cooks that it would make a meditating Buddha leap the wall of his temple compound to get to it.

Besides tea, major drinks include superb grain “wines” related to Japanese sake. Most famous is that of Shaoxing. Ningbo and other cities produce interesting and complex brews. These “wines” are technically beers or ales, being brewed from grain, but they are not carbonated, and they occupy the place in Chinese culture that wine does in Europe. They are brewed, however, in

a very different way: with a complex mix of ferments, involving species of yeasts and of fungi in the genera *Rhizopus*, *Aspergillus*, and others, as well as bacteria such as *Lactobacillus* (see Huang). Each brewery has its own strains and preparations. The resulting brews differ greatly from place to place, and have rich, complex, subtle flavors. They have inspired a gourmetship equal to that of tea, or of French wine. Of course, such “wines” exist throughout China, but those of the Yangzi delta are generally considered the finest.

**CHITLINS (CHITTERLINGS).** Chitlins or chitterlings, the small intestines harvested from a hog, are a frugal staple of myriad cuisines. After being soaked, thoroughly scraped, and cleaned, chitterlings have long been stuffed with forcemeats and spices and served as sausages. But chitterlings usage has never been limited to sausage making.

In England, cooks combine diced, sautéed chitterlings with mashed potatoes, form the mix into rounds, cap the resulting dumplings with grated cheese, and term the dish Down Derry. In and around Lyon, France, chitterlings, or *andouillettes*, are fried in lard or butter and served with vinegar and parsley.

No matter the cuisine or continent, chitterlings have long signaled linkage to the farm-based butchery of pigs. In rural districts worldwide, the cold weather killing of a pig and the removal of the chitterlings is a ritual of great import. In the American South, chitterlings, pulled hot from a cauldron of simmering water and eaten with a dose of vinegary or peppery condiment, are considered by many to be a reward for the hard work of farm-based butchery. This farm-to-table linkage has acquired special significance in the American South, where chitterlings (termed "chitlins" by most in an approximation of the prevailing pronunciation) have come to acquire a cultural importance that arguably exceeds traditional culinary usage.

In the book *Chitlin Strut and Other Madrigals*, the novelist and essayist William Price Fox of South Carolina asks the rhetorical question, "Who will eat a chitlin?" The answer: "You take a man and tie him to a stake and feed him bread and water and nothing else for seven days and seven nights, and then he will eat a chitlin. He won't like it, but he will eat it." Fox ascribes to the idea of chitlins as a marker of poverty. According to this often espoused rationale, chitlins and other pork offal products have long been a staple of the southern diet, and their presence was dictated not by preference but by a poverty-engendered creativity that could be claimed by all denizens of rural and impoverished southern districts.

White rural Southerners of the twentieth century, faced with the prospect of a rapidly industrializing and homogenizing region, doted on both boiled and deep-fried chitterlings. For these men and women, chitterlings served as both symbol and sustenance. By mid-century

there were active chitterling eating clubs, like the Royal Order of Chitlin Eaters of Nashville, Tennessee, and the Happy Chitlin Eaters of Raleigh, North Carolina. The traditional song "Chitlin Cookin' Time in Cheatham County" gives voice to the same:

There's a quiet and peaceful county in the state of  
Tennessee  
You will find it in the book they call geography  
Not famous for its farming, its mines, or its stills  
But they know there's chitlin cookin' in them  
Cheatham County hills  
When it's chitlin cookin' time in Cheatham County  
I'll be courtin' in them Cheatham County hills  
And I'll pick a Cheatham County chitlin cooker  
I've a longin' that the chitlins will fill

African Americans with roots in the rural South also claimed a specific cultural meaning for chitlins. At an early date, forced reliance upon offal marked the foods of black southerners with a meaning different from those of whites. Until emancipation, African American food choice was restricted by the dictates of white society. Despite these restrictions, perhaps even as a retort of sorts, African Americans fashioned a cuisine of their own. Laws may have been enacted to regulate slave dress and codify slave mores, but in the kitchen freedom of expression was tolerated, even encouraged. As a result, African American cooks reinterpreted traditional foodways in an African-influenced manner and claimed chitterlings as distinctly African American.

Chitterling imagery pervades African American culture. The informal circuit of juke joints and clubs patronized by African Americans has long been called the "Chitlin Circuit." The bluesman Mel Brown, a veteran of the circuit, chose to title his early 1970s greatest hits album *Eighteen Pounds of Unclean Chitlins and Other Greasy Blues Specialties*.

When soul food came to the fore in the United States during the late 1960s and early 1970s, chitlins—along with watermelons and okra—were celebrated as a cultural sacrament. But not all African Americans embraced chitterlings as a preferred marker of identity. "You hear a lot of jazz about soul food," observed Eldridge Cleaver in 1968. "Take chitterlings: the ghetto blacks eat them from necessity while the black bourgeoisie has turned it into a mocking slogan . . . Now that they have the price of a steak, here they come prattling about Soul Food."

The novelist Ralph Ellison understood how chitterlings functioned as both preferred cultural marker and liability. In the novel *Invisible Man* (1952), the protagonist imagines a scenario wherein he accuses Bledsoe, a pompous but influential educator, of a secret love of chitterlings:

I saw myself advancing upon Bledsoe . . . and suddenly whipping out a foot or two of chitterlings, raw, uncleaned, and dripping sticky circles on the floor as I shake them in his face, shouting: "Bledsoe, you're a shameless chitterling

eater! I accuse you of relishing hog bowels! Ha! And not only do you eat them, you sneak and eat them in private when you think you're unobserved! You're a sneaking chitterling lover!"

**CHOCOLATE.** Chocolate is the name applied to the variety of products manufactured from the seeds of the tropical tree *Theobroma cacao* L. The Swedish naturalist Carl Von Linné (1707–1778), known as Linnaeus, gave the tree the attribution *theobroma* or “food of the gods,” taken from the Greek. When adjoined to *cacao*, the indigenous Mixe-Zoquean term for the plant, the name is symbolic of the social, religious, and economic importance of chocolate in both New and Old World cultures. Yet while it was revered, it was also reviled, an ambivalence that attends chocolate even in the twenty-first century. Among all the fruits of tropical and subtropical America, why would this one elicit so much passion?

#### The Plant and Its History

The geographic origin of *T. cacao* is obscure. While most texts place its origin in either the Amazon or Orinoco River basins of northern South America, it is equally likely that a separate variety originated in Mesoamerica, perhaps in the Lacandón rainforest of the Mexican state of Chiapas. It has been hypothesized that wild *T. cacao* was broadly distributed in Central and South America and that at some time trees in the isthmus died out, leaving a northern variety and a southern variety to develop independently. The fruit of *criollo*, the northern variety, is characterized by elongated, deeply ridged yellow to red pods containing ivory or pale purple seeds, while *forastero*, the southern variety, is characterized by more ovoid, smooth, melon-like green or yellow pods with pale to deep purple seeds. The pigmented substances and related compounds in the cacao seeds impart bitter and astringent qualities to the chocolate. Hence the *forastero* variety has a robust flavor, while the delicate, “fine” flavor of the *criollo* is generally considered of superior quality. In the early twenty-first century, greater than 80 percent of commercial cacao was *forastero*, since this variety is hardier and more productive.

The word “cacao” seems to have come to the Maya from the Olmec, who inhabited the lowlands of the coast

of the Gulf of Mexico between about 1500 and 400 B.C.E. and who probably first domesticated the tree. The Izapán culture that bridged the Olmec and the Classic Maya (250–900 C.E.) likely planted the *criollo* plantations of Xoconochco (Soconusco) on the Pacific coastal plains of Chiapas, later a prize possession of the Aztec (Mexico) Empire. While this suggests that cacao was an important crop to the Olmec and the Izapán, it is not known to what extent chocolate was an icon food. The pre-Classic Quiché Maya of the Guatemala highlands apparently did not hold it in exceeding high regard for it is mentioned only in passing in the sacred *Popol Vuh* or “Book of Counsel.” But sometime before 250 C.E. this changed. Chocolate appears in Classic Maya iconography, where the glyph symbolizing cacao adorns ritual burial vases. Classic Maya, particularly the wealthy, imbibed cacao in betrothal and marriage ceremonies, reminiscent of the modern use of expensive French champagne. However, the ritual use of cacao reached its height during the time of the Aztec (Mexico) Empire between 1300 and 1521 C.E.

Cacao was both an elite drink and coinage among the post-Classic Maya and the Aztecs. Chocolate was considered a drink for warriors and nobles and had ritual significance as a symbol of human blood. Since cacao could not be grown in the Valley of Mexico, the site of the Aztec capital of Tenochtitlán, it had to be imported from either the conquered lands in Xoconochco or obtained by trade from the Maya of the Yucatán, which gave chocolate an exotic quality. It has been oft repeated that Motecuhzoma Xocoyotzin (the familiar “Montezuma”) drank fifty flagons of chocolate a day, most especially before entering his harem, but the account of the conquistador Bernal Díaz del Castillo says of those fifty large mugs, “he would drink a little” (Dillinger et al., 2000, p. 2058S). While cacao was an integral part of the beliefs and practices of the ruling Aztec elite, the image they held of it was not wholly positive. This warning is part of one Aztec tale: “You have become old, you have become tired because of the chocolate you drink and because of the foods you eat” (Coe and Coe, 1996, p. 80). The exuberance of the puritanical Aztecs for chocolate may have been tempered by its association with the luxury-loving Maya of the warm lands to the south. This north-south conflict was repeated in Europe.

In American English usage, “cacao” refers to the tree and its dried seeds prior to further processing; “cocoa” refers to the partially defatted, roasted, and ground cacao seeds; and “chocolate” refers to a food prepared from roasted cacao seeds. Although not leguminous, the cacao seeds are often referred to as “beans.” The composition of the edible cotyledon or “nib” is by weight approximately 55 percent fat; 30 percent carbohydrates, half of which is dietary fiber; 10 percent protein; and a host of minor nutrients. This breakdown provides a key to the basis for chocolate’s status as a luxury food.

Cacao seeds, numbering twenty to forty, develop within a thick-hulled pod surrounded by a white, sweet,

mucilaginous pulp that, with the potential to be fermented into ethanol, could have been what first attracted *Homo sapiens*. Wild cacao is dispersed by primates, who consume the sweet pulp and discard the bitter seed. *Cupuaçu*, a product made from the pulp of the fruit of *Theobroma grandiflorum*, a relative of *T. cacao*, is consumed by peoples of the Amazon. The preparation of cacao seeds for chocolate making begins with a fermentation step that at one point generates ethanol, which may explain why chocolate has at times been described as intoxicating. A “wine” produced from the liquid expressed from the cacao pulp is consumed in the Yucatán. It is speculative but possible that consumption of the cacao seeds was an afterthought, as the bitter flavor of the seeds is an acquired taste.

### Processing Cacao

Fermentation is required for the characteristic chocolate flavor to develop when the seeds are roasted. The mucilaginous pulp surrounding the seeds is fermented to ethanol, then progressively to acetic and lactic acids, which facilitates its removal. The acid and heat generated during fermentation kill the seed embryo, preventing germination and allowing enzymatic changes that generate flavor precursors and reduce bitterness and astringency. Following fermentation, the seeds are dried, preferably in the sun, to a final moisture content of about 7.5 percent. In this form, the seeds are transported from the country of origin to the major chocolate manufacturing regions.

For the Maya and the modern American alike, the conversion of the fermented and dried cacao to chocolate involves three major operations: roasting, winnowing, and grinding. Just as with meat, roasting cacao generates complex aromas appealing to the human sense of smell. Winnowing is the removal of the inedible shell surrounding the nib. Grinding, which the Maya accomplished by hand using a *metate* and for which later processors have used a variety of mechanical mills, liberates the cacao fat (cacao “butter”) from within the plant cells, extracts the aroma, and permits easy suspension of the cacao in beverages.

The quantity of protein in cacao is significant, and the amino acid composition, while limited in lysine and methionine, can be considered good for a protein of plant origin. However, unlike the leguminous beans that complement maize nutritionally, the digestibility of cocoa proteins is only about 16 to 17 percent. Therefore the proteins of cacao have little practical nutritional value.

The nitrogenous compounds of cacao include both proteins (80 percent) and the methylxanthines theobromine and caffeine, which are present in chocolate liquor (ground cacao nibs) at levels of about 1.22 percent and 0.21 percent respectively. They are both central nervous system stimulants, diuretics, and smooth muscle relaxants, although theobromine tends to be less so than

Chocolate swizzle sticks (*molinillo*). Mexico and Nicaragua, ca. 1800. Instead of pouring chocolate from a high position to create foam (the best part), the Spaniards copied indigenous forms of whisks to create foam on chocolate by spinning a stick between the hands. Both types of whisk are shown here. ROUGHWOOD COLLECTION. PHOTO CHEW & COMPANY.

caffeine. It is certainly reasonable to assume that the physiological effects of the plant alkaloids are part of chocolate’s appeal. Chocolate introduced Europe to these stimulants, though in a milder form than the coffee and tea that followed. The caffeine-containing kola nut, derived from an African tree of the same order as cacao (*Sterculiaceae*), became the basis of the American icon food Coca Cola. But it is likely that cacao butter is the soul of chocolate’s appeal.

While wild game, including deer, peccaries, monkeys, tapir, birds, reptiles, and smaller mammals, were abundant in the New World, the only domesticated animals routinely used for meat were the dog and the ocellated turkey (*Meleagris ocellata*). Muscle foods were not ordinary fare for the indigenous inhabitants of Mesoamerica, and “when the meat-eating Europeans arrived, they described Maya life as perpetual Lent” (Coe, 1994, p. 153). Perhaps just as significant, this lack of large domesticated livestock meant the Maya had no source of butter, lard, or tallow. Fats and oils have been sought for cooking, lighting, and medicine since the earliest times. Hence some of the earliest domesticated plant species in the Old World were the almond (*Prunus amygdalus*) and the olive (*Oleo europea*). Perhaps the well-documented Maya distaste for the fat of European animals resulted from Maya familiarity with the preeminent fat, cacao butter.

### Nutritional Value

Cacao butter is unique among natural fats. Its constituent fatty acids are principally the medium-chain saturated fatty palmitic acid and stearic acid and the monounsaturated oleic acid, so cacao butter exhibits a remarkable

Chocolate truffles are considered among the most luxurious of all chocolate confections. © C/B PRODUCTIONS/CORBIS.

stability against oxidative rancidity. Furthermore, the manner in which these fatty acids are distributed on the major molecule of natural fats, triacylglycerols, makes cacao butter solid at normal ambient temperatures, but it melts quickly just below body temperature. Bishop Diego de Landa reportedly said the Maya “get from cacao a grease which resembles butter, and from this and maize they make another beverage which is very savory and highly thought of” (Coe and Coe, 1996, p. 61). Fernández de Oviedo observed, “Cacao ground, and cooked with a bit of water, makes an excellent fat for cooking” (Coe, 1994, p. 54).

As in other fats, the caloric content of cocoa butter is high. Chocolate liquor contains approximately 520 kilocalories per 100 grams, 460 of which are from fat. The 1878 edition of *Encyclopedia Britannica* refers to “Cocoa, or more properly Cacao,” as “a valuable dietary substance” and points out that, while only infusions are made from coffee and tea, leaving large portions of their total weights unconsumed, the entire substance of the cacao seed is utilized. Henry Stubbe, in *The Indian Nectar, or, a Discourse Concerning Chocolata [sic]* (1662), reported that both English soldiers and Indian women in Jamaica sustained themselves for long periods by eating only chocolate yet did not exhibit a decline in strength. The nutritional qualities of chocolate have been praised by numerous authors since the sixteenth century, and some people have called it a complete food, like bread or milk, containing as much nourishment as a pound of beef. While this helped the Hershey Chocolate Company earn the Army-Navy E award for the Ration D, it caused much consternation within the Catholic Church. Twice the residents of Chiapas consulted Pope Gregory XIII on the question of whether or not drinking chocolate broke the ecclesiastical fast, and both times he responded that it did not because it was a drink. So while coffee and tea can

only be regarded as stimulant in effect, a cup of cacao is nutritive in value.

In preconquest Mesoamerica, cacao was an ingredient of a wide variety of drinks, gruels, and porridges, to which were added a great diversity of other flavorings, notably vanilla (*Vanilla planifolia*), chilli pepper (*Capsicum annum*), and “ear flower” (*Cymbopetalum penduliflorum*). It is likely that some of these concoctions were served hot and others cold. The simplest chocolate drink consisted of adding ground cacao and flavorings to water and agitating the mixture by beating or by pouring the liquid from one vessel to another to raise a foam, which was considered the best part of the drink and a sign of quality. During preparation the foam was reserved, then it was added back before serving. While the Maya added indigenous plants to augment the foam, modern consumers have replaced it altogether with whipped cream or marshmallow. The ground cacao was often ameliorated with ground maize or ceiba seed (*Ceiba pentandra*), though not in the most elite drinks. The bitter taste of most chocolate drinks was not immediately appealing to the European palate. Notable among the ingredients Europeans added to their chocolate are sugar and milk.

From at least the time of the Aztecs, people have been ambivalent about chocolate. Wolfgang Schivelbusch portrayed this ambivalence as a contest between diametrically opposed cultures: capitalist, middle-class, Protestant northern Europe versus aristocratic, Catholic southern Europe. Chocolate was a status symbol of the ancien régime, while coffee appealed to the bourgeois intellect. That chocolate became a status symbol in Europe had much to do with its richness, rarity, and exotic origins. As a status symbol, drinking chocolate vanished with the ancien régime. Cocoa became a breakfast drink for women and children; what formerly symbolized power and glory was now in the hands of the disenfranchised in middle-class society. However, at the same time, solid eating chocolate gained new significance as a luxury in its own right. Once again prestige followed the fat.

While the calories provided by chocolate may have been advantageous to a soldier on the march, the idle European nobility found it exceedingly fattening and disagreeable at times to the stomach. In search of a better beverage, Coenraad Van Houten in 1828 developed a means of partially defatting cacao using a mechanical press, an invention that had unanticipated consequences.

The development of solid eating chocolate was evolutionary. Chocolate liquor is solid below 85°F (30°C); formed into small pellets or wafers, it was issued to Aztec warriors on campaign. It was an obvious step to add spices and maize to the cacao during grinding and then form the mixture into cakes. These tablets could later be dispersed into water to prepare a beverage. Seventeenth-century texts mention “eating” as well as drinking chocolate, and recipes for solid confections containing cacao appeared in the eighteenth century. In the 1820s,

Goethe wrote of chocolate, "Enjoy this whenever it suits your mood, Not as a drink, but a much loved food" (Morton and Morton, 1986, p. 67). But it was the surplus cacao butter resulting from Van Houten's invention that accelerated the trend toward solid chocolate confections.

The addition of cacao butter to chocolate liquor made it possible to add more sugar to balance the bitterness of the cacao while still producing a thin paste that could be cast into a mold or used as a coating. Solid eating chocolate became an object of trade in the mid-1800s. However, these early products were coarse and gritty. Rudolph Lindt is credited with the 1879 invention of the conch that by grinding the sugar exceedingly fine and homogenizing the mixture creates a smooth and creamy textured chocolate with enhanced flavor and aroma. This "fondant" chocolate became a world standard.

Chocolate has been lauded for its purported medicinal value. Greater than one hundred medicinal uses for chocolate have been reported, and the majority fall into three main categories: 1) to aid emaciated patients in gaining weight; 2) to stimulate the nervous systems of apathetic, exhausted, or feeble individuals; and 3) to improve digestion, stimulate the kidneys (diuretic), and improve bowel function (Dillinger et al., 2000, p. 2057S). These uses can be explained either by cacao's caloric content or by the presence of methylxanthines. In the late twentieth century, attention focused on a class of compounds, phytonutrients, that tend to have antioxidant properties and are said to lower the risk of cancer and cardiovascular disease. Among these phytonutrients are the polyphenols, in particular the catechins, which have demonstrated physiological antioxidant properties. Pigment cells in the cacao seed, especially in the *forastero* variety, are rich in these compounds, which may mean redemption for the lowly cousin of the *criollo*.

Chocolate has long been called an aphrodisiac, a quality that entered into the debate over whether or not it could be consumed by Catholics during Lent, and references to its stimulation of the sexual appetite are numerous. Like other luxury items, chocolate is a symbol of excess wealth, but the association of chocolate and eroticism may not be entirely iconographic in nature. While no specific chemical compounds have yet been identified that could account for either chocolate's supposed addictive or aphrodisiac properties, debate continues on its physiological and psychological effects. Chocolate has become an essential ingredient in the act of seduction. It could be that the melting of the cacao butter in chocolate is symbolic of the melting of the heart and the breakdown of sexual resistance.

**CHOLESTEROL.** Cholesterol is one of the most widely disseminated organic compounds in the animal kingdom. Almost three hundred years ago, Antonio Vallisnieri observed that gallstones were soluble in turpentine or alcohol. Poulletier de la Salle, some thirty years later, demonstrated that the main constituent of gallstones could be crystallized from alcohol. This substance was thought to be a wax until 1815, when Michel Eugène Chevreul showed that it was not saponifiable and gave it the name "cholesterine" derived from the Greek *chole*, bile, and *steros*, solid. Soon thereafter, it was isolated from blood, brain, tumors, and egg yolk. The isolated compounds were shown to be identical. In 1843 Vogel found it in atherosclerotic arteries.

The chemical structure of cholesterol was elucidated over the years beginning in 1859. The compound was shown to contain a secondary hydroxyl group and a double bond. The exact empirical formula ( $C_{27}H_{46}O$ ) was established in 1888 by Friedrich Reinitzer. Proof of structure was obtained chiefly through the brilliant work of Adolf Windaus and Heinrich Wieland. The structure of cholesterol suggested by Windaus and Wieland in the 1920s was incorrect, but that does not detract in any way from their contribution. The true structure was established in the 1930s based on X-ray diffraction data.

There were many suggestions regarding the biological synthesis of cholesterol. The biosynthetic pathway became accessible with the introduction of radioactive carbon in the 1940s. The biosynthetic scheme was generally

elucidated by the work of Konrad Bloch, George Popjak, and John Cornforth. It was first shown that cholesterol could be synthesized in mammals and ergosterol in yeast from small organic molecules. Eventually it was shown that all twenty-seven carbon atoms of cholesterol were derived from the two carbon atoms of acetate. The methyl group of acetate contributed fifteen of the twenty-seven carbons of cholesterol and the carboxyl group contributed twelve. The pathway began with the condensation of two acetate residues to give acetoacetate and addition of one more two-carbon moiety to yield hydroxymethylglutaric acid (HMG). HMG lost a carbon atom and the resulting compound rearranged to provide an isoprene unit. Two five-carbon units combined to give a geranyl derivative that added another isoprene to give a farnesyl unit. Two farnesyl units united to provide squalene (C<sub>30</sub>H<sub>50</sub>), a hydrocarbon found in the livers of some species of shark that cyclized to yield lanosterol, a thirty-carbon atom sterol also found in sheep wool. In a series of rearrangements and demethylations, lanosterol yielded cholesterol. The key step in this complex synthetic pathway involves the reduction of HMG-CoA. Inhibition of HMG-CoA reductase is the basis of a number of potent new serum cholesterol-lowering drugs.

Cholesterol represents about 0.2 percent of the weight of the human body. As Table 1 shows, the bulk of the body's cholesterol is present in two tissues; one is the brain and nerve tissue, the other is muscle. In the brain, cholesterol is thought to act as an insulator, but there have been relatively few studies of the metabolism of brain cholesterol. The next large reservoir of cholesterol is muscle. Between them, nervous tissue and muscle carry 44 percent of the body's cholesterol. The cholesterol in these reservoirs turns over slowly.

Cholesterol is ubiquitous in the human body, where it plays structural and metabolic roles. Together with phospholipid, cholesterol is present in every cell membrane. In the adrenals, cholesterol is converted to adrenocortical hormones such as cortisone. In the gonads,

cholesterol is converted to the appropriate sex hormone—estradiol in women, testosterone in men. The cholesterol in skin is the precursor of 7-dehydrocholesterol, which is ultimately converted to vitamin D. The major catabolic products of cholesterol are the bile acids—cholic and chenodeoxycholic. These are designated as the primary bile acids; they are metabolized in the liver to deoxycholic and lithocholic acids. It has been estimated that over 90 percent of biologically synthesized cholesterol is metabolized to bile acids. In general, the body synthesizes more cholesterol than it ingests.

In 1912 Nicolai Anitschkow showed that cholesterol-fed rabbits developed aortic deposits similar to early human atherosclerosis. His experiments presented a possible explanation of human atherosclerosis and that particular debate has not yet abated. Simultaneously with Anitschkow's studies, A. I. Ignatowski demonstrated the atherogenic potential of animal protein, but compared to work on cholesterol and fat there has only been a desultory interest in protein effects.

Since Anitschkow's results were obtained by dietary manipulation, the view that dietary cholesterol was implicated in atherogenesis was accepted generally. With development of simple, rapid methods of cholesterol analysis, it became possible to screen populations for blood cholesterol content. Large epidemiological studies were launched and their results helped to develop the concept of risk factors for heart disease. Currently, the major risk factors are hypercholesterolemia, hypertension, smoking, obesity, and maleness. However, emerging data suggest that homocysteinemia and inflammation (due to infection with cytomegalovirus or *chlamydia pneumoniae*) are also important factors.

When cholesterol is ingested, it is emulsified with phospholipid and absorbed. The absorbed lipid circulates in the blood as a water soluble lipid-protein complex called lipoprotein. Initially, absorbed cholesterol is part of a large, triglyceride-rich particle called the chylomicron. In the course of circulation, the triglyceride is removed by activity of cellular lipases and the particles become smaller and their cholesterol content increases. The cholesterol-containing, lipid-protein complex consists of several fractions that are separable by virtue of their hydrated densities. In general terms, the four major fractions are the triglyceride-rich chylomicrons and very low density (VLDL), the cholesterol-rich low density (LDL), and the protein-rich high density (HDL).

Due to development by John Gofman of methods for ultracentrifugal separation of lipoproteins, researchers have been able to isolate and study lipoproteins. The cholesterol-rich low density lipoproteins (LDL) are thought to be major risk factors for coronary disease. It was demonstrated that oxidized LDL is the real villain in coronary disease. It also was shown that LDL can be subfractionated into small, dense and large "fluffy" particles. The small particles appear to infiltrate the artery preferentially.

TABLE 1

Distribution of cholesterol in a 70-kg man		
Tissue	Cholesterol content (g)	% of Total
Brain, nervous system	32.0	23
Connective tissue, body fluids	31.3	22
Muscle	30.0	21
Skin	12.6	9
Blood	10.8	8
Bone marrow	7.5	5
Liver	5.1	4
Heart, lungs, kidneys, spleen	5.0	4
Alimentary tract	3.8	3
Adrenals	1.2	1
Skeleton	0.7	—
Other glands	0.2	—

Researchers also know that the process of atherogenesis is not simple and is mediated by an array of small proteins. The high-density lipoproteins are about 50 percent protein. In the simplest terms, LDL facilitates entry of cholesterol into cells and HDL facilitates its removal. LDL receptors on the cell surface facilitate LDL uptake. The proteins of lipoproteins are very important because they provide recognition by cells, and it is now becoming evident that genetic differences in apolipoproteins may dictate susceptibility to disease as well as chances for the efficacy of medication.

The effects of dietary cholesterol became a concern shortly after Anitschkow's observation and warnings regarding excess levels of cholesterol intake, which constitute one of the foundations of dietary therapy. Since cholesterol occurs only in food of animal origin, it was a simple extension to seek an explanation of the role of cholesterol by examining the lipids of food from animal sources. Although no dietary fat is totally saturated or unsaturated, attention also turned to effects of fat saturation.

The amount of cholesterol in the average American diet is in the range of 300–350 mg/day. It used to be much higher. The levels of cholesterol in a number of common animal foods are given in Table 2. It is evident that most muscle contains about the same amount of cholesterol,  $81 \pm 7$  mg/100g. Cholesterol content of butter (per 100 g) is high, but we rarely eat more than 5–10 g of butter per meal. Shrimp is high in cholesterol but very low in fat. Eggs are also high in cholesterol. Continuing research nevertheless indicates that the cholesterol level of a food per se has little effect on serum cholesterol levels. The cholesterolemic effect is a function of dietary fat saturation. It has been shown that the absorption of cholesterol is more a function of the accompanying dietary fat than of cholesterol itself. Saturated dietary fat leads to higher cholesterol levels than does unsaturated fat. This observation is true for most people who are called "non-responders" (to dietary cholesterol). A small number of people are "responders," meaning they absorb more cholesterol, regardless of accompanying fat. In the late 1960s, Keys and Hegsted developed formulas for estimating changes in serum cholesterol based upon changes in dietary fat. There have been a number of more complex formulas developed, but the originals are referred to most often today. Essentially, they found saturated fatty acids to be hypercholesterolemic and unsaturated fatty acids to lower cholesterol. Stearic acid was considered neutral. The polyunsaturated fats lower cholesterol across the board so that HDL cholesterol (the "good" cholesterol) falls as does LDL cholesterol. Oleic acid seems to affect only LDL cholesterol. The reduction in total cholesterol may not be as profound, but the LDL/HDL cholesterol ratio is improved. Recent findings show that the structure of individual triglycerides may also influence their atherogenicity.

In summary, cholesterol is a substance that appears in all cells and also has a number of metabolic functions.

**TABLE 2**

**Cholesterol content (mg/100g) of selected foods**

Food source	Cholesterol (mg/100g)
Egg	504
Butter	250
Shrimp	150
Mackerel	95
Herring	85
Chicken	81
Turkey	74
Lamb	71
Veal	71
Beef	68
Pork	62
Flounder	50
Milk	15

It is synthesized in the body and is part of every cell membrane. Cholesterol is metabolized to adrenocortical or sex hormones, bile acids, and vitamin D. Levels of serum cholesterol are related to risk of coronary disease, but it should be borne in mind that cardiovascular disease is a metabolic disease, not one of cholesterol deposition. Dietary cholesterol is absorbed, but its effects on serum cholesterol are slight. Generally, there is an increase of about 2 mg of serum cholesterol for every 100 mg ingested. Cholesterol should be viewed as a chemical necessary for life and not as a toxic substance. As with so many other aspects of life, moderation is the key.

**CHOLINE, INOSITOL, AND RELATED NUTRIENTS.** Choline (2-hydroxy-*N,N,N*-trimethylethylammonium) and inositol (*cis*-1,2,3,5-*trans*-4,6-cyclohexanehexol) are water-soluble chemicals common in animal tissues and seeds of plants. Both compounds have been designated as water-soluble vitamins, and have also been referred to as “quasi-vitamins.” Choline and inositol, while having distinctly different chemical structures, are often discussed together because they are integral components of phospholipids, some of the most important lipids in both plants and animals. Two of the most important functions of phospholipids are as structural components of cellular membranes and as second messengers, transmitting signals through cell surfaces into the cell.

Choline and the phospholipid phosphatidylcholine (PC) are typically high in foods containing relatively high amounts of fat and cholesterol such as beef liver, beef steak, and eggs. Plant-based foods follow the same generalization in that those containing relatively high levels of fat also contain relatively high levels of PC (peanuts, soybeans, and so on). All foods contain some choline or PC. “Lecithin” is a term describing the commercially available phospholipids, which can contain a variety of compounds including free fatty acids, triglycerides, and most of the phospholipids. Estimates of lecithin intake in the American population are approximately 6 g/day and an accompanying 0.6 to 1.0 g/day of choline. Adequate levels of intake are 0.125 to 0.15 g/day choline for infants, 0.2 to 0.375 g/day for children, 0.55 g/day for adult males, and 0.4 to 0.55 g/day for adult females. However, intake of choline and PC is probably decreasing in the United States because of our changing food habits. As Americans decrease intake of fats from animals, their intake of choline and PC will also decrease. Maximum daily recommended choline is 16 to 20 g/day. No maximum intake level has been identified for lecithin, but 40 g/day has been tolerated. Reactions to excessive intakes of choline include nausea, perspiring, anorexia, and cardiac arrhythmias. Adults involved in strenuous exercise (such as participating in marathons) can experience significant decreases in plasma choline concentration (up to 40 percent), and there appears to be an enhancement of performance with supplemental choline intake. Commercially available sources of choline, lecithin, and PC are considered GRAS (generally recognized as safe) by the U.S. Food and Drug Administration.

Choline interacts with several drugs including anti-cancer drugs and nonsteroidal anti-inflammatory drugs (NSAIDs). Methotrexate is a relatively common drug in the fight against cancer and it leads to a decrease in liver choline concentrations and resulting increase in liver lipid concentrations. NSAIDs are known to facilitate changes in the gastrointestinal tract mucosal surface including perforations. Intake of PC improves such lesions.

Insufficient intake of choline can affect both acetylcholine and PC concentrations. Significant decreases in

acetylcholine can result in a condition known as tardive dyskinesia (impaired movement and defective neural transmission), which can be corrected by increasing choline intake. There is also interest in choline as an aid in alleviating short-term memory loss (for example, Alzheimer’s disease) and some concern that chronic inadequate intake of choline may facilitate the onset of Alzheimer’s. Deficiencies of PC can result in increased lipid concentrations in liver (hepatic lipidosis), which is an analogous condition to cirrhosis of the liver caused by chronic alcoholism. If the deficiency persists, cirrhosis eventually leads to carcinoma. Choline deficiency also leads to infertility, bone abnormalities, hypertension, impaired kidney function, and decreased hematopoiesis. Similarly, deficiencies of inositol in laboratory animals leads to hepatic lipidosis and alopecia (hair loss). An inability to break down PI (Niemann-Pick disease) leads to enlarged spleen and liver, as well as mental development abnormalities.

Phospholipids are antioxidants commonly used in food products to inhibit oxidation and as emulsifying agents. Phosphatidylcholine can bind minerals such as iron and copper that are considered prooxidant minerals, or those that facilitate oxidation of lipids. Phosphatidylcholine can also help degrade hydroperoxides, or partial breakdown products of lipids and is commonly used for this purpose. The nitrogen-containing phospholipids phosphatidylethanolamine and phosphatidylserine (PI) are even more active than PC in protecting against oxidation of lipids. The two most common sources of phospholipids are soybeans and egg yolk. Lecithin from soybeans is more commonly used in commercial applications because of its lower cost. Soybean lecithin contains 50 to 70 percent phospholipid and is extracted with other prooxidants in vegetable oil processing. This process separates the oil from phospholipids, vitamin E, and other potentially beneficial nutrients. An older mechanism of lipid separation has been revived in the United States using simple pressing of soybean seeds to remove the oil instead of solvents. This results in oil with high levels of vitamin E and phospholipids. Lecithins containing higher concentrations of phospholipids and PC are also becoming available.

## CHRISTIANITY.

*This entry includes two subentries:*  
Eastern Orthodox Christianity  
Western Christianity

### EASTERN ORTHODOX CHRISTIANITY

Food plays an important role in the liturgical, ritual, canonical, and dogmatic life of the Eastern Orthodox Church. Throughout the ages, Orthodoxy—from the Greek *orthós* (correct) and *dóxa* (belief)—has come to encompass many nationalities throughout the world. Historically the early church was geographically separated into a Latin West (centered in Rome) and a Greek East in Constantinople (modern Istanbul). The Roman emperor Constantine, who sanctioned tolerance of Christians in 313, moved his capital to the Greek city of Byzantium (and renamed it Constantinople) in 330, and convened the first Ecumenical Council there. Although the Catholic Church and the Orthodox Church remained in communion through the Seventh Ecumenical Council, the Great Schism of 1054 is the generally accepted date for the division of the Christian churches.

The Russians, Ukrainians, and White Russians (also referred to as Belorussians or East Slavs) were proselytized by Orthodox missionaries beginning in the ninth century, and eventually adopted the liturgy, calendar, and many customs of the Greek Orthodox Church. (While the Slavic Orthodox and some "old calendarist" Greeks follow the older Julian calendar, non-Slavic Orthodox,

The five main *prosforo* which are consecrated during the *proskomidia* at the beginning of the Greek Orthodox communion. Shown here are the signs on the pieces that are taken from the communion loaf: 1) the *prosforo* for St. Charalambos, 2) the *prosforo* for the Virgin Mary, 3) the nine-part *prosforo* for the saints, 4) the *prosforo* for the living, and 5) the *prosforo* for the dead. Original drawing by Tatiana Voronina.

such as most Greeks, Syrians, Egyptians, and the Balkan nations, have followed the contemporary Gregorian calendar since the early part of the twentieth century. Dual dates are given throughout this entry.) Despite the multiethnic and multilingual composition of Orthodox Christians worldwide, Orthodoxy remains united in dogma, virtually unchanged for almost two thousand years. There is a similar unity in the role that food plays in the life of the church.

### Holy Bread (*Prosforo*, *Antidora*, *Artos*)

Holy bread, or *prosforo* (from *prosfora* 'offering'), plays a central role during Communion, the most important rite of the Orthodox church. For Orthodox Christians, the *prosforo* (Russian *prosvira*) becomes the Body of Christ. Often prepared by a parishioner, the bread is round and consists of two separate parts made from leavened wheat bread. The stamped design on the upper part of the loaf is that of a cross with the letters IC, XC, NIKA, which stands for "Jesus Christ Conquers," and is cut out by the priest during the preparation of the Eucharist ("thanksgiving"). The service of *artoklasia* (breaking of bread) represents a thanksgiving for God's blessings and commemorates Christ's miracle of multiplying five loaves to feed thousands. Other sacred breads include *antidora* (from *dōra*, 'gift'), which is distributed by the priest to the faithful following the Divine Liturgy, *artos*, *panagia*, and Easter cake (Greek, *tsourekí*).

The commandment to sacrifice bread is found in the Old Testament: "Besides the cakes, he shall offer for his offering leavened bread with the sacrifice of thanksgiving of his peace offerings" (Leviticus 7:13). In

accordance with ancient traditions, a least five *prosforo* are used during the first part of the liturgy (*proskomidia*). The wheat used to make the *prosforo* is symbolic of the human essence, which consists of the many elements of nature; the yeast represents the life-giving force of the Holy Ghost. The division of *prosforo* into two parts is symbolic of the distinction between human flesh (flour and water) and soul (yeast and Holy Water). Traditionally, the *prosforo* is prepared by pious women and widows.

It is customary for Orthodox who are named after a particular saint to celebrate their “name day.” In Greece and Cyprus the celebrant provides the five *prosforo* to their church on the eve of the saint’s day. The small round loaves of white bread, which are spiced with cloves and bitter orange-blossom water, are then blessed by the

priest, and one of the loaves is sent to the *yortaris*, or feast giver, while the other loaves are cut into pieces and offered to the congregation and to the poor.

*Antidoron* (Greek) or *antidor* (Russian) is a small piece of *prosforo* that is distributed after a mass to those who did not receive communion. *Antidoron*, from the Greek *anti* (instead) and *dōron* (gift), dates to the seventh century in the Orthodox church.

*Artos*, the third type of sacred bread, includes an image of the cross with a crown of thorns, which is symbolic of Christ’s Resurrection. A leavened bread that is consecrated by the priest on Easter, the *artos* remains on the lectern before the iconostasis during the week. Easter cake is a kind of *artos* that is consecrated on Saturday before Easter Sunday.

Bread appears in various customs of the Orthodox church. Orthodox monasteries celebrate a ceremony to the Panagia (the Virgin Mary) in which sacred bread—*prosforo* or *panagia*—is solemnly taken to a refectory after the liturgy, reminiscent of the apostolic tradition. Special breads also mark periods of Orthodox fasting. For Greek Orthodox, Lenten fasting begins on “Clean Monday,” when a special flat bread called *lagana* is baked. Among Russians, Ukrainians, and White Russians there was a custom of baking an unleavened bread with the image of a cross during the fourth week of Lent.

### Orthodox Feasts and Fasts

Various Orthodox feasts and fasts mark the life of Christ, the Virgin Mary, and the saints. The Orthodox Church recognizes twelve Great Feast Days, eight of which are events in the life of Christ, and four in the life of the Virgin Mary. Easter stands alone as the most important Orthodox holiday, and is celebrated on the first Sunday after the first full moon following the vernal equinox. (The date is calculated on the Julian calendar and therefore differs from that of Easter in the Western Church.) Feasts like Christmas are fixed, while others such as Easter are moveable.

**Easter.** Special Easter bread and boiled eggs that are dyed blood red (symbolic of Christ’s crucifixion) are the

most important food items for Orthodox during the Easter season. In Greece a large loaf of leavened bread is always present on the Easter table together with traditional sweet rolls (*koulouria*), sweetened bread (*tsoureki*), and little filled cheese envelopes (called *kaliitsounakia* on the island of Crete).

The tradition of presenting Easter eggs has its roots in the ancient notion of the cosmic Golden Egg. Early Christians regarded the egg as a symbol of life, and rebirth was made manifest through the Resurrection of Jesus Christ.

Following the midnight Easter service—held on Saturday night—the Greeks have the traditional *Anastasimo* meal, the first meal of the Resurrection, which consists of a special paschal soup (known in Greek as *mayeritsa*) made from the intestines and other organs of lamb. The soup is eaten in the early morning following the midnight service, along with the sweet bread called *tsourekia* (flavored with the spice *machlepi*, which is made from a ground seed from Syria), *koulourakia pascalina* (bread rolls), the *kalitsounia* (cheese pies), and a salad of greens. The red-dyed boiled eggs, which are prepared on Holy Thursday, are cracked by faithful Greek Orthodox accompanied with the words *Christos Anesti!* (“Christ is Risen!”) and the reply *Alithos Anesti* (“He is truly Risen”). The Easter Sunday meals consists of spit-roasted lamb, salads, grilled offal, Easter rolls and bread, and red wine.

Russians, Ukrainians, and White Russians celebrate Easter by preparing sweet bread (Russian *kulich*; Ukrainian *paska*) and sweet curds with raisins or fruits (*pasha*) and by painting boiled eggs that have been consecrated. East Slavs dye eggs by boiling them with onion husk or fuchsine. Ukrainian Easter eggs are famous for their decorative art and symbolic designs.

**Christmas and New Year.** Christmas (25 December/7 January) is the second important festival in the Orthodox calendar. Roasted pig was an obligatory dish in the Orthodox tradition, but it has been superseded by stuffed roast turkey for Christmas Day, doubtless influenced by the customs of Western Europe. Turkeys are stuffed with a mixture of minced beef or lamb, rice, and pine nuts and served with a variety of salads and potatoes. During the Christmas season Greek cooks prepare *loukanika* (sausages) and *lountza* (smoked fillet), *hiromeri* (smoked ham), and *zalatina* (brawn). The Greeks also eat rose water-flavored shortbread and syrup-drenched honey cakes called *kourambiédes* and *melomakárona*, respectively.

A New Year tree is symbolic of the Tree of Life in Slavic Orthodox cultures, and is decorated with candles denoting the spiritual light and fruits implying the kingdom of paradise and its salutary fruits in Greece. The feast of St. Basil is celebrated on New Year's Day, and on New Year's Eve the head of the household cuts the *vasilopita* (literally "bread of the king"). The first slice is laid aside for Jesus Christ, and then everyone receives a slice; a lucky coin is traditionally hidden somewhere in the loaf. (The recipient of the coin is said to enjoy good fortune for the coming year.) This custom is repeated by town officials as an expression of the wish for good health and prosperity for the whole community. The story of the *vasilopita*, or the loaf of St. Basil (the Great; 330–379), dates to an incident in ancient Cappadocia (in central Anatolia), when the Archbishop Basil was said to have

saved the church treasury from plunder by baking coins in small loaves that were then distributed to the whole congregation.

**Other major feasts.** The Holy Trinity (in Greek, *Aghia Triada*) is celebrated on the fiftieth day (the Pentecost) after Easter. Russians, Ukrainians, and White Russians historically decorated their houses with branches of birch tree, green grass, and flowers imitating an ancient harvest tradition. In Greece, on the Saturday before Pentecost, sweet cereal porridge, sweet bread, and other foods are consecrated in the church and then brought to cemeteries where they are distributed to the poor. There is a similar tradition among East Slavs.

Many Orthodox consecrate both grapes and wheat on the feast day of the Transfiguration (6 August/19 August) as an expression of thanksgiving. In Russia, where grapes are not cultivated everywhere, a related feast (of the "Apple Savior") sanctifies apples and other fruits and vegetables in the church.

### Fasting

Fasting among Orthodox Christians has its basis in the Old Testament and has ancient roots in the Church. Orthodox insist that the body must be disciplined as well as the soul, and strict fasting in the Orthodox Church is demanding, especially when compared to the fasting known to some Western Christians. Extended and one-day fasts, which are linked to major Christian feasts, account for more than two hundred days of the year. There are four extended fasts in the Orthodox tradition, but their duration and the level of strictness vary. The Great Fast of Lent begins seven weeks before Easter; the Fast of the Apostles starts on the Monday eight days after Pentecost, and ends on 28 June (11 July), the eve of the Feast of Saints Peter and Paul; the Assumption Feast lasts from 1 to 14 August (14 to 27 August); and the Christmas Fast lasts forty days, from 15 November to 24 December (28 November to 6 January).

Each of the major fasts has associated foods and food traditions, but there is great variation in the duration, severity, and exceptions made (for example, monks and clerics versus the laity, the infirm versus the healthy, and so on.) In fact, there is great variation in the strictness of fasting among Orthodox worldwide, and dispensations, especially among the Orthodox diaspora, are common.

The last week before Lent is marked by carnival or Shrovetide, a celebration that dates from ancient times and has much in common with the cult of the deceased. In Greece the pre-Lenten period is called *Apokries* (literally "away from meat"). Devout Orthodox visit cemeteries with sweet wheat porridge (called *kolivo* in Greek) and other foods. In Russia the period before Lent is known as *Maslenitsa* (or "Cheese Week"), and during this time quantities of *bliny* (pancakes) and milk products, especially butter, are eaten in place of meat products. In Russia, on Saturdays before the feasts of St. Trinity and St.

Dimitry, as well as other days, a special sweet porridge (*kutja*), similar to the Greek *kolivo*, and made from cereals with honey, raisins, or fruits, is blessed during the liturgy. Such rituals are closely connected with the ancient beliefs of farmers that treat the souls of the deceased with grain, wine, oil, honey, and *panspermia*—a porridge made from cereals and leguminous plants.

During Lent, only vegetable-based foods are permitted: meat, fish (with backbone), dairy products, eggs, and sweets are specifically excluded from the diet. On Saturdays and Sundays dishes containing vegetable oil (except on Saturday of Holy Week) and wine are permitted. The greatest severity in fasting is reserved for Holy Week, when Orthodox around the world abstain from all animal products, oil, and wine. On Great Friday (Good Friday), in particular, devout Orthodox eat nothing in preparation for the church services.

Strict one-day fasts occur on Christmas Eve, when East Slavs consume nothing but bread and water until the conclusion of the evening mass (when they eat a special porridge called *sochivo* made with boiled wheat, barley, or rice with honey); on the eve of the Epiphany or the Twelfth-Day (5 January/18 January); on the Feast of the Beheading of St. John the Prophet (29 August/11 September); and on the Feast of the Exaltation of the Holy Cross (14 September/27 September). In addition, Orthodox faithful fast on Wednesdays and Fridays every week (with some days excepted).

Historically in Russia, peasants who grew their own crops and vegetables were better able to endure times of fasting than those in urban areas. “Black” or rye bread and pies made from the mixture of rye and wheat flour were a part of the everyday meal. A variety of cereals allowed the peasantry to prepare different kinds of nutritious porridges. Potatoes, cabbage, and carrots were cultivated in many provinces and were the main ingredients of traditional soup or *shchtee*.

In every family the customs of fasting were passed on from generation to generation, but there was notable differentiation even within one family. Elderly people were the authority in the practice of fasting and abstained more strictly. Children were trained to fast from the age of two or three years. The larger part of the population in Russia kept fasts.

During the Soviet period (1917–1991) the tradition of fasting was compromised in Russia by Communist Party doctrine that held organized religion a suspected enemy of the state. Adherents of the Orthodox faith nevertheless carried on these practices despite official intolerance.

## WESTERN CHRISTIANITY

Christianity traces its origins to the life and preaching of Jesus, a Jew living in Palestine in the first century of the Common Era (C.E.). He taught that all humans are children of God and need to repent of their sins. According to Christian sacred writings, recorded in the New Testament, he was put to death by the Roman colonial authorities but was brought back to life three days later. Christians believe that he was the son of God, and that his death and resurrection save them from sin and death.

Christianity began as a movement within Judaism but quickly spread outside the Jewish community; by the late fourth century it was the official religion of the Roman Empire. During the Middle Ages, there was theological and political conflict between the followers of the patriarch in Constantinople and the followers of the pope in Rome, leading to a split between the Western Church and the Eastern Church (also known as the Eastern Orthodox Church) in 1054. In the sixteenth century, the Western Church divided still further between Roman Catholics and a variety of Protestant groups. Although

Unlike Eastern Christianity, the Latin Church developed numerous powerful orders, each with its own dietary rules. The order known as the Teutonic Knights originated during the Crusades and became the most powerful military force in Christianity. The headquarters of the order, shown here at Malbork (former Marienburg), Poland, is one of the largest brick castles in Europe. The account books outlining the order's daily food expenses still exist and offer valuable insights into the complexities of the medieval kitchen. © PAUL ALMASY/CORBIS.

separated into hundreds of large and small groups, Christianity is now a global religion. As it has spread, it has encountered other cultures and belief systems. In the process, Western Christianity has assimilated its early practices, which were shaped by first-century Judaism, with those of its host cultures. This assimilation has influenced its food practices.

### Ritual Food

One food ritual stands at the center of the religion. Christians believe that on the night before his death, Jesus gathered with a small group of followers for a meal, which, according to the Gospels of Matthew, Mark, and Luke, was a Jewish Passover dinner, but according to the Gospel of John was a *berakah* (blessing) before the Passover. Presiding over the meal, Jesus, in prayerful thanksgiving, proclaimed that the bread and wine were his body and blood; he enjoined his followers to repeat this repast in his memory.

Christians today still reenact that meal, under a variety of names. Catholics call this ritual of reenactment the Mass or Eucharist (from a Greek word meaning "thanksgiving"). Protestants call it the Eucharist, the Lord's Supper, the Last Supper, Holy Communion, or simply Communion. In early Christianity it was a real

meal with a full menu, sometimes known as an *agape* (love feast). Now the ritual is celebrated as part of the worship service with only vestiges of the meal; worshipers generally eat only a small piece of bread and drink a small amount of wine or grape juice. Instead of emphasizing food, the ritual focuses on words; participants retell the story of Jesus' life and death and thank God for his salvation.

While sharing this general framework for the Eucharist, different groups of Christians carry out the ritual in different ways. In fact, many of the divisions between Christians are rooted in the different beliefs and practices regarding Communion. Throughout Christian history, believers have engaged in theological disputes as well as actual warfare over the proper celebration of the ritual.

Roman Catholics believe that the Eucharist is a sacrament, a ritual that connects them with God. For them, celebrating the Mass is a repetition of Jesus' self-sacrifice in his death; they believe that receiving Communion will help them reach salvation. In the course of the ritual, Catholics believe, the bread and wine become the body and blood of Jesus. The food attains a distinct and profound holiness. The Catholic Eucharist is very formal; the same words and gestures are used wherever it is celebrated. Specially trained and ordained priests must lead the ritual, using only wine from grapes and wheat bread. Catholic churches celebrate the Mass at every Sunday service; many congregations celebrate it daily. Episcopalians and Lutherans also believe that the Eucharist is a sacrament. Certain Episcopal churches—known as Anglo-Catholic or "High Church" parishes—are very close to the Roman Catholic Church in their beliefs and practices.

In contrast, some Protestant groups—Baptists, for instance—believe that Communion is simply a remembrance of Jesus, without any direct impact on an individual's salvation. The bread and wine remain bread and wine, serving as reminders of Jesus' death but not actually becoming his body and blood. The meal symbolizes the partakers' union with God and with each other. For these Protestants, Communion lacks the formality of the Catholic Mass, and their Communion practices can differ significantly from one place to another. In some cases, lay Protestants can lead the ritual, and it is not uncommon for some Protestant churches to administer grape juice instead of wine. Many of these groups celebrate Communion only three or four times a year. Other Protestant groups occupy a middle ground between the Catholics and the nonsacramental Protestants. They believe that Jesus is somehow present in the meal, but not that the bread and wine have become his body and blood. In their churches, Communion is a slightly more formal service, celebrated perhaps once a month; it is increasingly common in the Lutheran church for communion to be celebrated every Sunday.

Like observers of other religions, Christians also practice domestic food rituals. Many Christians, for instance, pray before meals, giving thanks to God for the food. Some churches also bless farmers' crops and animals. Particularly in the United States, many churches organize informal fellowship meals for their members, designed to strengthen the community within the church.

### Taboos, Fasts, and Feasts

Since Christianity began as a movement within Judaism, many of its practices—including those involving food—are variations or adaptations of Jewish ones. Judaism has clear guidelines on proper eating behavior, including a taboo on certain “unclean” foods (pork and shellfish, for example) and rules for the preparation of other foods. In the first century C.E., Christians argued over whether they had to abide by Jewish law. There is little in Christian scripture that requires adherence to such food taboos; several texts explicitly free believers from previous laws. Nevertheless, some Christians retained the Jewish dietary laws, while others held that Jesus' teachings did away with these restrictions. Since the latter group became dominant, Western Christianity has no formal food taboos.

Some small groups do shun certain foodstuffs, based on their interpretation of Jesus' teachings. The Manicheans (members of an early Christian movement condemned as heretics by the Catholic Church), for instance, required vegetarianism. The Seventh-Day Adventists also discourage the eating of meat, while members of the Church of Jesus Christ of the Latter Day Saints (Mormons) avoid caffeine. These and several other groups also discourage the drinking of alcohol. Other than these semiofficial taboos, however, Christianity has little impact on believers' daily diets.

Christian fasting practices have changed over time. Like their Jewish brethren, early Christians fasted twice a week—but on different days. As Christianity grew, fasting became less common among most Christians; the practice was more frequent among religious elites, like monks and nuns. During the Middle Ages, particularly ascetic Christians would abstain from any food—except the Communion bread and wine—for months at a time. Most Christians, however, observed the penitential season of Lent—the forty days (not including the Sundays) before Easter, the spring festival commemorating Jesus' resurrection. Rather than fasting, most Christians would abstain from meat or some other luxury. The medieval Church also introduced a weekly fast, requiring all members to abstain from meat on Fridays, observing the day of the week on which Jesus was killed. After the sixteenth-century Reformation, newly formed Protestant groups abandoned many of the fasts, although some continued to fast during special times of prayer and penitence. Fasting is rare in modern Protestantism, although some Protestants fast as a spiritual-physical discipline. In recent decades, the Roman Catholic Church has loosened its fasting directives.

### THE BOOK OF COMMON PRAYER (1979)

We celebrate the memorial of our redemption, O Father, in this sacrifice of praise and thanksgiving. Recalling his death, resurrection, and ascension, we offer you these gifts. Sanctify them by your Holy Spirit to be for your people the Body and Blood of your Son, the holy food and drink of new and unending life in him. Sanctify us also that we may faithfully receive this holy Sacrament, and serve you in unity, constancy, and peace; and at the last day bring us with all your saints into the joy of your eternal kingdom.

While early Christians adopted some of their practices from Judaism, they replaced Jewish feasts with their own set of holidays, tied to historical events in the life of Jesus. The most important ones are Christmas (December 25), marking his birth, and Easter Sunday (a movable feast that can fall from March 22 to April 25), observing his resurrection. These have become major celebrations both in the Church and in Christian societies; in many cultures, the holidays have become secularized as days for shopping and gift giving. Whether Christian or secular, food remains an important part of the holidays, often celebrated by large family meals. There are no common menus for these feasts, however; the meals are determined by the local culture rather than by the religion. In some parts of the United States, for instance, turkey is traditional fare for Christmas and ham for Easter, but other regions and other countries have their own menus.

### CORINTHIANS 11:23–25

For I received from the Lord what I also handed on to you, that the Lord Jesus on the night when he was betrayed took a loaf of bread, and when he had given thanks, he broke it and said, “This is my body that is for you. Do this in remembrance of me.” In the same way he took the cup also, after supper, saying, “This cup is the new covenant in my blood. Do this, as often as you drink it, in remembrance of me.”

*(Revised Standard Version)*

## Charitable Food

Like many other religions, Christianity puts a great deal of emphasis on the importance of charity. It inherited from Judaism the requirement to help feed the hungry. In the first few centuries, Christians would invite hungry strangers to join their shared meals. Certain church leaders, called deacons, were responsible for making sure that widows, orphans, and other poor people were fed. Later, monks and nuns established hospices where the hungry and travelers could stay and eat. In the middle of the twentieth century, Western Christians established agencies to help feed the hungry. They opened soup kitchens and food pantries to feed the urban poor. They also raised money to send to countries where natural disasters and poverty threatened starvation. The acquisition and distribution of food and food-related supplies for the needy continues to be among the most visible practices of modern Western Christian charity.

**CHRISTMAS.** The word "Christmas" means the mass of Christ and is the name for the Christian observance of the nativity of Jesus on 25 December. In liturgical importance, Christmas was originally in fourth place, following Easter, Pentecost, and Epiphany, yet in terms of popular observance it has become the most important feast day of the year and the basis for a vast commercial retail industry derived from it, even in countries like Japan and Korea, where Christianity is not the predominant religion.

The early Christians were not initially concerned with the Nativity of Christ, and even in the fourth century C.E. it was not a universally fixed observance among Christians. The choice of 25 December is considered arbitrary and not based on evidence provided in the New Testament, the Christian text dealing with the life of Christ. Many theories have been put forward for the choice of the 25 December as Christ's Nativity, but that

it fell during Roman Saturnalia is now largely dismissed. It appears to have been fixed in relation to Epiphany (6 January), counting backward twelve days (now the twelve days of Christmas) or thirteen nights by the lunar calendar. It also falls three days after the winter solstice, a date when a number of pagan gods underwent resurrection after the shortest day of the year. This includes Sol Invictus of the Roman state religion during pagan times, a cult associated with the deification of the emperor. Whatever the explanation, it is evident that the early Christian Fathers, in their struggle for political and psychological supremacy, turned the *interpretatio romana* (the process of romanizing foreign gods) on its ear by expropriating a number of pagan symbols and observances and providing them with new Christian meanings. For this reason, Christmas and especially the foods associated with it represent a fusion of diverse pagan strands varying widely in emphasis from one country to the next. The celebration of Yule in Scandinavia has become one of the most distinctive aspects of the holiday as observed in northern Europe. The tradition of St. Nicholas of Myra in the Netherlands and the Franciscan cult of the Bambino Gesù in Italy are examples of the many forms these fusions have taken. All are expressed symbolically in food.

The mass and the various mystery plays dealing with the Nativity and the ales, or community-wide feasts, were the core of the old observance. The mass was often preceded by abstinence, a period called the vigil, that was then broken at midnight with a large meal in which the entire village or community participated. Such midnight feasting was practiced in many predominantly Roman Catholic countries, such as Poland and Spain, into the twenty-first century.

Tin cookie-cutter dating from about 1900 makes twelve cookies at once. The cookies are small and therefore could be used as Christmas tree decorations. ROUGHWOOD COLLECTION. PHOTO CHEW & COMPANY.

Outside of the church but parallel to its liturgies existed the folk customs carried over from pagan beliefs. Thus the ales exhibited a prevalence of mumming (playful imitations of old gods and their stories), antlered beings, pigs (associated with butchering, of course), and other oral traditions given the shape of festive breads and cakes or reflected in the choices of certain foods, such as roast goose, or dishes containing blood, such as blood soups, blood sausages, and black puddings, from which English plum pudding and mincemeats evolved. In the Orthodox tradition of the Eastern Church, which broke with Latin practice, Epiphany remained the official Nativity of Christ, and dishes containing blood are fully absent from the diet, festive or otherwise.

The late Middle Ages retained community feasting, although it became more centered on the manor house, a practice later continued on the plantations of the American South, while in towns it moved into the private homes of wealthy merchants and the nobility. The Protestant Reformation, with its emphasis on individual salvation, broke down the old community-wide feasts in favor of the family and home. This shift brought a widespread erasure of older village and folk customs (in England and northern Germany, for example) and the rise of the commercial Christmas. Gingerbreads, marzipans, and various festive foods hitherto made and sold by monks or by nunneries, moved into the general marketplace and become available to anyone with the financial means to purchase them. Dutch paintings from the seventeenth century often depict domestic feasts that present holiday foods in great abundance. In Protestant areas, the alms formerly associated with Christmas doles for the poor disappeared and did not return until the rise of urban missionaries in the nineteenth century.

The American Christmas, the primary theme of this article, inherited its major characteristics from England during the colonial period. Some religious groups, such as the Puritans of New England and the Quakers of Pennsylvania, abjured the observation of Christmas altogether on the theological basis that the day was fixed artificially by the early Church and therefore was not a real holiday. The Puritans originally created Thanksgiving as a substitute for Christmas. Thanksgiving subsequently became attached to the Christmas holiday, more or less marking the commercial beginning of the Christmas season.

Other American regionalisms gradually emerged into mainstream custom. The Christmas tree, with its huge array of food ornaments, first appeared among the Pennsylvania Dutch in the form of table-top branches of cherry trees (which were forced to bloom) or a large limb from an evergreen shrub, such as mountain laurel or cedar. These table-top trees were set into large flower pots and surrounded with plates of festive food. The shift to small table-top trees is well-documented by the 1790s, and their appearance in store windows is noted in a number of newspapers during the 1820s. Later, in the 1840s, the Christmas tree custom was further reinforced by Ger-

This hand-tinted picture depicts an old type of Christmas tree set up on a table. The woman is decorating the tree with jumbles (ring cookies), gingerbread animals, marzipan cherries, and small baskets of candy. Her husband is holding a large package of toys under his arm. WOOD ENGRAVING FROM THE PICTORIAL SCRAP BOOK (PHILADELPHIA, 1860), ROUGHWOOD COLLECTION.

man immigrants, and it quickly became a symbol of status in Victorian households. While its origins are undoubtedly pagan, the tree was adopted by many churches during the Sunday School movement of the 1840s and 1850s as a means of teaching Christian values to children.

Likewise, during the revival of medieval themes led by the Oxford movement in England, St. Nicholas (called Santa Claus in America), the old gift bringer of the New York Dutch, underwent a complete rejuvenation, especially after his popularization in newspapers and magazines by the immigrant artist Thomas Nast. Thus by the beginning of the twentieth century the American Christmas had acquired a new and much less liturgical focal point, that is, Santa Claus and the exchange of gifts, including a tree under which the family displayed symbols of its economic well-being.

Throughout these evolutionary changes, the basic foods of the American Christmas remained the same, especially the format of the Christmas dinner. The dinner is based on eighteenth-century English models, and at its

centerpiece is a roast, normally turkey. This centerpiece is surrounded by side dishes reflecting regional tastes and often ethnic backgrounds. Italian families may add a dish of pasta, although in households adhering to a more traditional Italian fare, the “five” fishes are served. African-American families may feature sweet potatoes and cowpeas, and Mexican-American families may incorporate a salsa and the custom of breaking a piñata, which culminates the festivities on Christmas Eve. The traditional explanation for the piñata custom is that the image symbolizes the devil, and, by breaking it, he is destroyed. The act is thus rewarded by a shower of good things to eat. However, the custom of creating a shower of plenty has numerous parallels with other pre-Christian fertility rites, most of which are associated in some manner with Christmas. The earliest recorded Christmas trees (in seventeenth-century German guildhalls) were left ornamented with food until Second Christmas (December 26) or New Year’s Day, when they were shaken violently to shower the food on a mob of happy children. In other parts of Germany and central Europe, apple trees were shaken on Christmas Eve to ensure that the trees would bear a good crop of fruit.

The Christmas Day meal continues to evolve as newer immigrants add their own symbolism to the old theme or as older groups create new variations, as in the case of Kwanzaa of African Americans. Ethnic nuances aside, the basic meal focuses on roast turkey, repeats much the same meal format as Thanksgiving, and finishes with a variety of traditional desserts, including pumpkin pie, mincemeat pie, and fruit cake. It has been said that the unchanging quality of the Christmas dinner has endeared it to Americans, who find a sense of continuity in its year-to-year repetition.

**CHRISTMAS DRINKS.** Christmas is celebrated at the time of the winter solstice, and in the passage from one year to the next. The hopes and fears triggered by these two dates in the world’s calendar have shaped the customs that cluster around Christmas itself, while the

joy of that festival has cast a glow over the entire season. In the course of centuries, many ingenious ways have been devised to defy the darkness, feast on the bounty of the year’s harvest, and perform good-luck rituals, half in jest and half in earnest, to ensure health, happiness, and abundance in the next twelve months. Christmas calls for a tightening of social bonds, and an enlargement of social sympathies. Drink, with its power to raise spirits and relax constraints, plays an important part in the characteristic ceremonies of the holiday.

A touch of extravagance, indeed excess, matches the spirit of the season and marks many traditional Christmas drinks. France and Spain may be content with a fine champagne or the best wine available, but other countries favor more elaborate concoctions. Wassail and punch in Britain, heated mulled wine in cold northern countries, and their cooling equivalents in the warmer south have one characteristic in common. They are mixed

“Bringing in Christmas,” depicts a romanticized Victorian recreation of medieval English Christmas festivities. Prominently featured is a huge bowl of wassail, itself a symbol of Christmas merriment. Wood engraving from *Christmas Poems and Pictures* (New York, 1866). ROUGHWOOD COLLECTION.

drinks, in which some combination of sugar, spice, and fruit juice has been added to the principal ingredient, whether that be ale, cider, or wine, while in certain cases the whole has been given an extra kick with a shot of brandy or bourbon, rum or gin. Eggnog, the old American favorite, starts life as a blend of eggs and cream, but this blameless nursery food is transformed into nourishment for grownups by a potent blend of sugar, spice, and spirit.

Whatever its components, the Christmas drink has ceremonial and symbolic functions. It is a pledge of goodwill to present company and absent friends. Indeed, the name of the oldest toast in Britain, "Wassail," is derived from the Middle English words for "be well." Sometimes the ritual takes the form of toast and response; sometimes the drink is shared as a loving cup passed from one person to the next so that each can share its contents in a companionable way. In local traditions throughout the Christian world, wine has been blessed at Christmas by the church, and cider has been poured on apple trees to encourage next year's harvest. The permitted breakdown of normal social barriers in this special season is played out in small, symbolic dramas. The master of a household will prepare eggnog with his own hands and offer it to his servants. Strangers may carry a wassail bowl to any door and assume the right of entry and reward.

There is nothing immutable about any Christmas tradition. At the core is always joyful celebration, but the ways in which that sentiment is expressed are infinitely variable, depending from age to age and place to place on ingredients locally at hand, and on the tastes and fashions of the time. Anything may be acceptable, as long as the message stays the same: "Merry Christmas!"

**CHUTNEY.** Chutney is a term applied to a variety of spicy relishes and condiments in Indian cookery. The term itself is an anglicized form of the Hindi word *chatni*. In India, there is an implied understanding that these preparations are also freshly made from fresh ingredients. For example, chutneys using nutmeg are prepared only when nutmeg is in season, although chutneys can be composed of a wide variety of ingredients and thus represent many types of flavors and textures. In general, chutneys fall into two distinct categories: freshly-made preparations for immediate consumption, and cooked preparations intended to keep as long as a year, which can be grouped further according to their saltiness, sweetness, sourness, or spiciness. Many recipes combine several elements of these basic flavors, and textures range from coarsely chopped preserves to smooth sauces. Conceptually, they blur the neat distinction made in Western cooking between preserves and pickles.

Some of the most common chutneys in India are those made with mangoes, coconut, sesame, peanuts, or the ground leaves of herbs, especially mint or coriander. Chutneys are served as condiments (side dishes) at Indian meals, and historically were only eaten on special occasions such as weddings or by the rich. Since Indian independence from Great Britain in 1947, the technology of canning in glass jars has now made commercial chutneys widely available throughout the country at affordable prices. Traditional cooked chutneys made for home consumption were generally infused or slowly cooked in the hot Indian sun over a period of several days until they attained the right flavor and consistency. This method is still employed in modern India in homes which do not own stoves. In fact, many cookbooks written for Indians make no mention of stoves. For example, in Aroona Reejsinghani's *Indian Pickles and Chutneys* (1977), a Kerala region chutney made from jackfruit (a relative of the breadfruit) specifies solar cooking for one week.

Indian cookbooks devoted to chutneys generally arrange the recipes according to region, since chutney styles are strikingly different in various parts of the country and among different religious groups. The various flavors and textures are of special importance to Hindus. A few of these are worth mentioning: mango, plum, apple, and apricot chutneys, and various murabbas (fruit in thick syrup) from West Bengal; garlic, sweet and sour mango, and peanut chutney from Uttar Pradesh; dry fish, shrimp, and onion chutney from Kerala; pork sepetel and shrimp ballachong from Goa; kanji, tomato and jeera chutney from Punjab; tamarind chutney from Haryana; hot mango chutney, guramba, and panchamrit from Maharashtra; chundo and hot lime chutneys from Gujarat; guava and eggplant chutneys from Himachal Pradesh; Nagaland fish chutney; and the various Jain, Parsee, and Sindhi chutneys defined by religious dietary rules. In fact, the murabbas (also written morabbas) evolved out of the Unani system of medicine and owe their origin to Indian contact with the Arab world.

Made mostly from salted limes and garlic, Lucknow chutney (or Lucknow sauce) was a popular condiment in nineteenth-century England and America. It was commonly served at hotels and appears on many menus from the period. The chutney was sold in fancy ceramic jars like the one shown here dating from about 1876. COLLECTION OF THOMAS NEFF.

The first Indian chutneys to reach the West appeared as luxury imports in England and France during the late 1600s. They were mostly mango chutneys put up in sticky syrups and shipped in ceramic pots. These luxury goods soon served as models for Western copies which appeared in cookbooks as “mangoed” fruit or vegetables. The most popular substitutes were unripe peaches or melons. However, by the nineteenth century, many chutneys were manufactured in India specifically for export to Europe, among them Lucknow Chutney (a purée of salted limes), and various brand-name chutneys like Major Grey’s or Bengal Club. All of these export products were created from recipes appealing to British rather than to Indian tastes, meaning that they were generally sweet and lacked the intense flavors, saltiness, or peppery heat preferred by Indians.

**CIVILIZATION AND FOOD.** If by “civilization” we mean the culture of cities, assumed to have emerged with the Bronze Age, in about 3000 B.C.E., then food was the decisive factor in terms of both production and consumption. Before this time, in the farming revolution of the New Stone (Neolithic) Age, crops and animals that have continued until today to provide much of human food had been domesticated. This represented a shift from hunting and gathering, from the collection of wild plants and animals, to food raised under the control of humans, leading to a great increase in the population. The bulk of cultivated foods (cereals) came from the domestication of local grasses, hitherto gathered in their wild state; root crops and vegetables proved more of a problem to grow, and fruit cultivation appeared only later on.

The Bronze Age saw another formidable move forward. The strength of animals was harnessed to wheeled transport and to the plow. Complex irrigation systems were developed. A further great increase in food production thus became possible. The animal-drawn plow enabled an individual to cultivate considerably larger areas of land; wheeled transport meant that the surplus could be shifted more easily; and irrigation in the sun-drenched lands of the Near East, India, and China again brought about increased yields, especially of rice but also of the other main Neolithic cultigens, wheat and barley. A parallel change took place in Mexico, centering on maize (corn).

These various changes led to increased production and therefore to population expansion, but they also led to socioeconomic differentiation. With hoe (manual) agriculture and a plentiful supply of land, it had hardly been profitable or indeed possible to employ others to work, except under conditions of slavery.

Landholding before the Bronze Age had been relatively egalitarian, as had food production. Most households had a roughly similar supply of food, as indeed had been the case with earlier hunter-gatherer regimes, in which the sharing of food was institutionalized to a high degree. With the plow, that equality disappeared rapidly.

One man could cultivate a much larger area than another; the acquisition of additional land became a way of maintaining a higher standard of living, not only paying agriculturalists to perform work but also using the surplus to exchange with local specialists, or to obtain luxury goods from traders. Those luxuries included culinary delicacies imported from elsewhere, particularly those that could withstand travel, such as cheese from the Massif Central of France brought to Rome, or sugared foods carried from India to China, or wine and olive oil shipped throughout the Mediterranean.

What has been called the urban revolution of the Bronze Age, giving rise to civilization in the form of cities, enabled societies to use their food surpluses to support full-time specialists; this meant the development of activities that included trading, metalworking, and writing. Trade and transport opened up distant and different food supplies and resources; metalworking and the use of ovens made possible new modes of food preparation, such as the baking of bread; and writing led to the elaboration and transmission of more complex recipes, and eventually to the emergence of a differentiated—even a high—cuisine, the latter occurring in China, in India, in the Arab and Muslim world, and later, with the Renaissance, in Italy and France. But hierarchical differences in diet aside, greater agricultural productivity meant that a society could supply a larger number of people, a proportion of whom could be engaged in activities not connected with the production of essential foodstuffs. Among other things, town dwellers required the large-scale transport of food, to markets as well as restaurants and other eating places outside the house. It was China with its vast cities that first experienced the rise of a restaurant culture, as well as the emergence of prepared foods, such as tofu (bean curd), sold in the marketplace.

### **Food and Class**

Initially such developments affected only the rich and high-status groups. For this change in food production meant an increase not only in population but also in differentiation between owners of large estates, peasants cultivating their own fields, and the newly emergent stratum of landless laborers. A similar degree of socioeconomic stratification emerged in urban areas. These “classes” were now marked not only by differences in amounts consumed, as had long existed in the under hoe cultures, but also by qualitative differences in styles of life, with largely in-marrying subcultures, conserving their particular practices. The rich had access to dishes and drinks unavailable to the poor, either because of their lack of economic power or because of sumptuary legislation (or indeed of internalized preference or “taste”). Such differences were elaborated on and conserved in cookbooks originally compiled for the households of nobles and rich merchants and taken up more widely only with the coming of the printing press and the flowering of the urban middle classes in the sixteenth and seventeenth centuries.

This process of democratization was the result of the industrialization of prepared foods that could be said to have effectively begun with the invention of bottling by Nicolas Appert in France (1806) and its subsequent expansion into canning, especially in America during and after the Civil War, which altered the whole economy of food, interposing the grocer and later the supermarket between the producer and the consumer. Not only the industrialization of food preparation was involved but advances in food production itself, with changes in farm practice. For example, the rotation of crops and the use of manure had been adopted early on in the medieval period. The nineteenth century saw not only mechanization but also the coming of artificial fertilizers and chemical sprays and the more rapid transformation of crops by seed selection and finally by manipulation of the genes of crops, and above all the shift from the use of animal energy (which began with the plow) to that derived from mineral (fossil fuel) sources. Water of course had long been significant for food production, especially in arid regions. Its early control gave rise to extensive irrigation schemes with their heightened productivity (and problems of distribution, dangers of salinization and soil exhaustion), and later on it could be harnessed to provide the power for mills to grind grain and, much more recently, for other manufacturing processes, including the generation of electricity as a new source of power. But the basic activities of cultivation, such as plowing, were not affected by the use of waterpower nor yet by that of coal, which transformed other forms of production, leading up to the First Industrial Revolution. Farming was radically changed only with the advent of the use of gasoline in the combustion engine, during the Second Industrial Revolution, and the introduction of tractors and then of combine harvesters, inventions that affected the whole use of manpower on the land, freeing labor (and sometimes creating unemployment) as well as transforming villages from productive communities to ones dominated numerically by commuters, pensioners, and holiday makers. If by “democratization” we refer not only to political arrangements but also to the diffusion of products to the mass of the people, the transformation of small luxury into larger consumer cultures, then these changes in the production of food were as important as the changes in manufacturing and employment with which they were associated.

### **The Modern World**

Despite enormous recent increases in world population, levels of food consumption per capita have risen rather than fallen in most regions. Owing to the Green Revolution and the adoption of “improved” plant varieties, with improved water control and fertilizing, famine has become less frequent in India and China. That is not true, however, of Africa, where total food production has decreased in relation to population growth and to consumption, mainly because the production of food is still

based on the hoe; the plow (together with animal traction and elaborate water control) crossed the Sahara only recently, and its use remains scattered. Regional food deficits are largely made up through trade and aid, allowing imports of food from the surpluses of the more productive regions of the world (especially North America). The overall increase in well-being has been substantial, at all levels of society, with better health for most inhabitants—albeit with obesity and other food-related ills for some. Such productivity increases have always depended on the deliberate modification of crops, but recently the capacity to increase production by chemical means (such as adding hormones to beef), and to manipulate genes directly, has given rise to fears about the effects on human health and on our relationship to the natural world. People have always been concerned about their intake of food, fearing poison, sorcery, adulteration, and other modes of interference that might compromise their physical or mental health. That is nothing new, but these fears have grown with our capacity to intervene—that is, with the growth of civilization.

**CLASS, SOCIAL.** Social class or social stratification is defined by unequal access to desirable resources (such as money, goods, and services) or personal gratification

(such as prestige or respect). The sociologist Max Weber argued that social class was a function of differential wealth, political power, and status. The various dimensions of social class have different influences on food consumption and its consequences. Income and wealth provide access to food or constrain food purchases. Education provides knowledge, skills, and beliefs that shape food desires and place constraints on food choices by means of information acquisition and food preparation. Occupation not only represents prestige but also structures time and constrains the attention that can be given to food. Occupation-generated work hours and lifestyle choices affect what is eaten as well as where and with whom food is eaten.

Distinctions are made between classes. The lower class (often referred to as “working class” or blue-collar workers) is generally associated with people with low levels of education, unskilled or semiskilled occupations, and low income. Middle-class people (often seen as “white-collar” workers) generally have more education, usually having graduated from high school or college, hold technical or mid-level managerial positions, and earn average to above average incomes. Upper-class people tend to have high education, the highest salaries, and the most prestigious occupational positions.

The whole notion of taste, as refined food sensibilities, is class-based. Members of lower classes often strive to emulate the taste and taste practices of higher classes, who in turn attempt to change their notions of taste and eating behavior to maintain the distinction between themselves and those perceived as of lower status. Thus, what, where, and when food is eaten is shaped by social class in many societies. Historically, members of the lower class have found many of the foods of the wealthy to be strange if not disgusting. (Such stereotyping, however, applies equally to both groups: while the so-called lower classes might find raw oysters disgusting, the middle or upper classes might find roast goat equally unpalatable. These kinds of tastes—or distastes—evolve over time and cultures and are not fixed.) Members of higher classes have come to identify certain foods with impoverished status. For instance, after World War II, chicken became associated with low income and was eschewed by the wealthy because of this association. Currently whole-wheat or brown bread tends to be consumed more by people of middle- or upper-class background; by contrast, bread prepared with processed wheat (white bread), which is less expensive, is more often the choice of working-class consumers. The reason for this difference is a historical reversal of fortune. The white flour was once that of the elites, who would even color it with alum. The highly refined flour was reserved for those with great status, whereas the whole-grain flours were those of the poor. Beer is the alcoholic beverage of the working class—the exception being pricey imported beers, microbrews, and gourmet beers that are popular with “yuppies”—while wine, particularly wines with a lin-

An American postcard from circa 1900 taking a humorous aim at upper-class table manners. ROUGHWOOD COLLECTION.

eage, tend to be the choice of individuals of upper-middle and upper-class backgrounds.

Restaurants were once a place where only the upper class would dine, while today persons of all classes eat in restaurants. However, the choice of type of restaurant and the frequency of eating meals out varies by social class. Part of this difference is a function of income. Those with higher salaries or greater wealth can afford to eat out more frequently and to visit more expensive restaurants. Use of restaurants, however, is also a function of attitudes, which themselves vary by social class. Those in blue-collar positions are more likely than those in white-collar jobs to perceive eating out—in restaurants, that is, not fast-food establishments—as something that is done for pleasure. Those with higher incomes, university degrees, and white-collar positions seek more variety in restaurant fare. Interest in eating a variety of ethnic foods, an indication of cultural cosmopolitanism, is also more frequent among those with greater education, income, and occupational prestige.

The desire to imitate those of higher social class background is practiced by some individuals, and restaurants play a role in this phenomenon. Restaurants with expensive dishes with a cosmopolitan atmosphere are sometimes the choice of people who wish to exhibit the consumption of the upper class. At the same time, differences in consumption represent a routine form of social dominance exercised by upper-middle and upper-class members. Thus, efforts of the lower-middle class to imitate upper-class behavior are met by changing behavior among the upper class. New, more exclusive restau-

rants are often sought in attempts to maintain a class distinction in restaurant patronage.

Class background is also associated with the use of meals as a form of entertaining friends. As income and education rise, so does the likelihood of entertaining friends by feeding them a main meal. Those with white-collar positions are more likely to entertain friends by having them over for a main meal, though this generalization may apply more to urbanites; poor folk in the country often have big dinners, where everyone brings something potluck-style. Low-income families not only lack the money to provide such entertainment but may also inhabit housing that lacks the space to feed many people at one time. Among the very low-income, space may be so limited that the family itself cannot sit down to a meal together. Eating in the homes of kin is not a function of class, but eating with friends and coworkers is: professional and managerial classes are more likely to eat in the homes of friends than those in working-class occupations. When it comes to cooking, those with more education and income are more likely to be willing to experiment with new dishes or dishes of their own creation than are those with less income and education.

Social class background makes a difference in the food-related lifestyles practiced by many people. In addition, people's life chances are affected by their social class. The poor tend to devote high percentages of their household budgets, after paying rent, to food, yet generally have to settle for lower-quality food items and a more monotonous diet. Obesity is far more likely among persons of low income than persons in higher income

groups. In more economically developed countries, the poor are more likely to experience food insecurity or food insufficiency, and in less economically developed countries, the poor are more likely to experience various nutrient deficiency diseases.

**CLIMATE AND FOOD.** Throughout most of prehistory, humans acquired food by hunting, fishing, gathering, foraging, or scavenging. The animals and plants they consumed were native to the local climate and environment and provided highly variable diets. Arctic and subarctic populations fished, gathered shellfish, and hunted land and sea mammals; temperate forest populations gathered seasonal plants and hunted wildlife; prairie and savanna dwellers hunted and trapped large mammals; and tropical forest dwellers fished, gathered a variety of plant foods, and hunted small mammals. Climatic influences on the flora and fauna included in the local diet were rainfall, temperature, seasonality, and longer-term

cooling and warming trends. The most extreme climate changes were the Pleistocene glacial advances and retreats in the northern hemisphere. Climatic variation in temperature and precipitation became central to food procurement when plants and animals were first domesticated about ten thousand years ago at the end of the Pleistocene epoch.

There are only a few small populations that subsist entirely on hunting and gathering of wild plants and animals, although many populations continue to supplement their diets with wild foods. An exception to this is the fish and shellfish that provide substantial amounts of food to people through commercial fishing. Nevertheless, most peoples around the globe consume domestic plants and animals that are grown or raised locally or are produced commercially.

#### Climate and World Biomes

Climate (general, longer-term) and weather (specific, short-term) tend to structure ecosystems around the world by regulating rates of plant photosynthesis and production and contributing to patterns of vegetation and animal life. The principal factors are temperature, which is largely a function of global latitude and elevation; precipitation, drainage, and stored fresh water resources; windflow, which can dry or chill; solar radiation; and seasonal patterns in all of these, particularly temperature and rainfall. Polar and subpolar ecosystems, which are unsuitable for agriculture, are characterized by cold winters, cool summers, and limited precipitation. Some livestock are kept in polar and mountain ecosystems: llama and alpaca in the Andes, yak in the Himalayas, reindeer in the Arctic. Temperate and subtropical zone ecosystems may have relatively high precipitation, marked seasonality in temperature, and agricultural growing seasons up to six months. Drier temperate continental ecosystems (prairies, steppes) are also highly seasonal in rainfall with cold winters. Relatively dry, temperate zones can be highly productive with the practice of irrigation. Mediterranean ecosystems (including California, Chile, and parts of the Near East) have cool, wet winters and hot, dry summers. Many of the major cereal crops of the world were domesticated in these seasonally dry, temperate, or Mediterranean ecosystems: maize or corn in Middle America, wheat and barley in the Near East, rice in Asia, and sorghum in Africa. Quinoa, a member of the goosefoot family, was domesticated in the cool, seasonally dry reaches of the Andes. Tropical ecosystems have warm temperatures throughout the year but often with seasonality of rainfall. Those ecosystems with limited and seasonal rainfall grade into tropical grazing lands or savanna, while increased rainfall yields forests from sparse woodlands up to densely wooded rainforests. Widespread rainforest agriculture today includes a form of shifting, swidden, or slash-and-burn cultivation. Within each of these broadly-defined ecosystems or biomes, there is consid-

erable variation: variation by season and by year, with inherent risks to livestock and agricultural production. For example, dramatic heat waves or cold periods, droughts, floods, hailstorms, and hurricanes can destroy crops and domestic livestock, producing a loss in food security and even famine. These extreme events have a major impact when they occur in heavily populated areas.

### World Biomes and Food Production

Plants and animals were first domesticated in the seasonally dry Mediterranean climate of the Fertile Crescent in the Near East. These farming and livestock practices then spread along the Eurasian east-west axis zone of similar latitude and climate. Most domestic seed plants (e.g., cereals, goosefoots) and pulses (e.g., beans, lentils, grams, peas) were temperate-zone domesticates, whereas some tubers and root crops were domesticated in the tropics (e.g., manioc, yams, taro). With the discovery of the New World by Europeans, many native American foods spread to parts of the Old World: the potato became a staple in temperate zones of Europe and the Himalayas; maize became a staple in the drier African tropics; manioc became a staple in the wetter African tropics. Other New World temperate-zone domesticates, such as chocolate, peanuts, and tomatoes, became favored foods around the globe.

Today, temperate and subtropical agroclimatic zones of the United States, Argentina, Europe, and eastern Asia (China and Japan) still have the highest productivity of domestic grains and livestock that feed a substantial portion of the world. This results from a favorable combination of sophisticated agrotechnology and climate. Figure 1 illustrates how climatic inputs interact with the flows of information and resources in a Western industrialized system of agriculture.

Temperate and subarctic marine biomes are highly productive sources of fish and shellfish, although these food resources are in decline because of effective commercial exploitation by Western nations.

### Food Intake and Climate

Some patterns of food intake are indirectly or directly linked to climate. For example, tropical populations are often limited in protein intake. Solomon Katz (1987) noted that this occurs in traditional agricultural populations dependent on grains (maize, rice, sorghum, millet) or tubers (potato, manioc) that are high in calories, but relatively lower in protein. Among tropical forest dwellers, as in the Amazon and the Congo basins, protein must come from fish, insects, some game animals, and plant foods. A direct effect of climate is the high metabolic need for calories in arctic or subarctic zones and temperate zone winters because of increased energy needs for temperature regulation in the cold. Derek Roberts (1978) documented that arctic dwellers have an elevated basal metabolic rate (BMR), which may be adaptive in the cold. Infants who are kept under cool condi-

tions have higher food calorie requirements for normal weight gain than infants kept under warmer conditions. In Western industrialized nations, reduced activity levels during the winter season lead to unhealthy increases in the accumulation of human body fat (and weight) or energy storage. On the other hand, the accumulation of body fat in Ama women who dive for edible seaweed throughout the year allows them to withstand the cold water off the shores of Korea and Japan.

### Climate Change and Food Production

An alarming trend that is certain to influence human patterns of food intake is recent climate change. Some variation in weather and climate is normal. Yet within the past 250 years, however, increased atmospheric carbon dioxide (CO<sub>2</sub>), resulting from fossil fuel combustion, deforestation, and agricultural activities, has led to a “greenhouse” effect and global warming. A major compilation of research by Houghton and other scientists from the Intergovernmental Panel on Climate Change (IPCC) in 2001 has demonstrated beyond any reasonable doubt that human activities have produced a 1.1°F (0.6°C) rise in average global temperature over the past 150 years (see Figure 2). And by the year 2100, this global temperature is expected to rise another 1.8 to 6.3°F (1.0 to 3.5°C), a change that is greater than any experienced on the globe within the past ten thousand years.

Global warming will have variable effects on local weather and climate that are dependent on latitude, elevation, and geographic location. For example, McCarthy and others (2001) have shown that sea level rise from melting glaciers during the twentieth century has been about 6 inches (15 cm), and a projected rise during the twenty-first century is an additional 18.9 inches (48 cm). This will contribute to a loss of coastal agricultural lands and an increased salinization of water and coastal lands. Influences on agricultural food production are likely to be pronounced. Higher temperatures will cause rises in rainfall and the likelihood of floods in some areas and declines in rainfall and consequent drought in other areas: extremes in weather events (floods, hurricanes, heat waves, droughts) will be more common. Both conditions will lead to crop losses and decreased plant productivity. There will be increased heat stress in livestock leading to lower milk and meat production. At the same time that coastal agricultural and grazing land will be lost to sea level rise and salinization, the human population will continue to increase, putting greater pressure on food resources.

It is estimated that the impacts of global warming will be greatest in those regions of the world such as Asia, Africa, Latin America, and the Pacific Islands, where the adaptive capacity is low and vulnerability is high because of the lack of economic resources. Africa is likely to be especially hard hit because such a large part of its land resources is arid or semi-arid savanna lands. Of the total desertification and degradation around the globe, nearly

30 percent is in Africa. Although the debate continues on whether overgrazing, overpopulation, or warming trends are the cause of desertification, nevertheless, global warming will certainly increase the expanse of dry lands on this continent and elsewhere.

Humans have a remarkable capacity to adapt to change, including climate change, through culture and technology. Global warming and its consequent negative effects on our capacity to produce food will be an unprecedented challenge to this adaptability.

**COCKTAIL PARTY.** The cocktail party is a social gathering, held early in the evening, usually for a period of about two hours, typically from 5:00 to 7:00 P.M. or 6:00 to 8:00 P.M. It may take place in the home, in a food-service setting such as the private room of a restaurant or hotel, or in a business such as an art gallery or bookstore. Cocktails, wine, and soft drinks are served, though contemporary cocktail parties may in fact offer wine and soft drinks exclusively and skip the cocktails. In any case, beverages are accompanied by finger foods, which are meant to delight the palate, stave off hunger until dinnertime, and complement the cocktails.

Depending on variables such as the host's budget and degree of formality desired, the cocktail party may be catered or prepared at home, drinks may be mixed and served by a bartender, or the host may act as bartender.

Servers may be employed to pass around hors d'oeuvres or the host may simply pass them around or arrange them on a buffet.

Certain physical and social behaviors on the part of the guests characterize cocktail parties. Normally, guests are not seated, but remain standing. Drinks in hand, they mill about, socializing to the strains of music, typically an instrumental arrangement, solo piano, or vocal jazz, played at a volume that encourages conversation. Rather than allowing participants to engage in deep and lengthy discourse, the social aim of the cocktail party is for guests to participate in small talk. At purely social cocktail parties, friends catch up or become reacquainted; new friends are introduced. At business-related cocktail parties, new contacts are made, business cards exchanged, and connections renewed.

#### History of the Cocktail Party

The cocktail party is a modern invention, conceived in the 1920s. Before World War I, most home entertaining was quite formal: people hosted teas, dinners, and balls. After 1918 informal entertaining became much more accepted.

In 1920 when the Eighteenth Amendment put Prohibition into effect, public consumption of liquor was driven underground into the speakeasy, and brought for the first time into the home. Before that, Americans may have served wine at dinner, but the consumption of hard liquor was generally confined to the tavern; and women, for the most part, did not drink alcohol at all. Speakeasies, in an attempt to compete for business, created fanciful cocktails, heretofore unknown in the United States, and even welcomed women. Those Americans who made their own spirits at home ("bathtub gin") adapted these new cocktail recipes for home use. A boom in the manufacture and sales of bar accessories ensued, including cocktail glasses and shakers.

For the power players in the business world, the drinks are secondary to the networking and the sealing of deals. Even with lawyers present, everyone always smiles. © PAUL BURTON/CORBIS.

A simultaneous explosion in the importation of fancy canned foods, such as olives, anchovies, and smoked oysters, encouraged people to serve hors d'oeuvres incorporating these comestibles along with their cocktails. Friends came to call before dinner, as was the habit, and the cocktail party was born. When Prohibition was repealed in 1933, American zeal for the cocktail party only increased, encouraged by idealized depictions of cocktail parties in motion pictures.

With the post-World War II economic boom, cocktail parties became institutionalized as an appealing way to entertain friends at home. In addition, it became a form of business entertaining brought into the home. The man of the house (typically the sole wage-earner) would invite his employer and his wife, along with friends, coworkers, and other acquaintances; the woman of the house would act as hostess. Women wore "cocktail dresses," the knee-length sleeveless sheaths that are still in fashion.

The popularity of the cocktail party waned in the 1960s, with the rise of the counterculture. It began to see a renaissance in the mid-1980s, though at that time it was taken out of the home. Cocktail parties became popular forums for celebrating art gallery openings, book publications, product launches, and other commercial ventures. The 1990s saw a resurgence of cocktail parties given in the home, fueled partly by young adults who found the kitsch value of cocktail culture appealing.

Although the cocktail party is a purely American institution, it has been exported around the world, adopted by many other cultures. In France, for instance, the cocktail party is known as *le cocktail*.

### Food and Drink

Hors d'oeuvres may be hot or cold, passed around, or placed on tables. Traditionally, cocktail party foods have tended toward the salty and fatty, encouraging the consumption of cocktails. At contemporary cocktail parties, traditional hors d'oeuvres from other cultures frequently appear—from Caribbean cod fritters to sushi. So do ingredients and techniques from other cultures used in new ways—for instance, tuna tartare canapés or mini-pizzas. Hors d'oeuvres tend to be more or less elaborate depending on whether the party is given at a business or a home, and whether they are prepared at home or catered.

Traditional cold hors d'oeuvres include boiled shrimp with cocktail sauce, smoked salmon, caviar, and olive canapés. Cold hors d'oeuvres incorporating vegetables, such as endive leaves filled with herbed goat cheese, have become popular.

Meatballs, *rumaki* (skewered chicken livers wrapped in bacon), shrimp toast, and hors d'oeuvres made with puff pastry are traditional hot cocktail party hors d'oeuvres, but today anything from Italian rice dumplings to mini "burgers" made of seared foie gras might be served. Skewered, grilled foods have become popular, including Thai satés.

The less powerful gather in the office over Chablis and potato chips to discuss résumés, rumors of downsizing, dysfunctional elevators, and the cost of MBAs. PHOTO BY RICHARD RADSTONE. © RNT PRODUCTIONS/CORBIS.

Classically, the beverages served were cocktails in the strict sense of the word, that is to say a spirit combined with bitters (or a bitter element such as vermouth), and perhaps sugar and/or water (sometimes in the form of ice). Examples of this would be martinis, Manhattans, Old-Fashioneds, Rob Roys, and champagne cocktails. Contemporary cocktail party beverages would be cocktails, especially cosmopolitans and martinis, liquor served straight-up or on the rocks, wine, champagne, and sparkling mineral water. Beer is generally avoided.

In the 1920s little single-subject recipe books began to appear, featuring recipes for cocktails and/or finger foods, many, but not all of them, published by liquor companies. These books grew in popularity with the cocktail party itself, culminating in a large number of titles published in the 1950s. Their publication died down until the mid-1980s, when a few titles appeared; by the mid-1990s they had reemerged as a significant subgenre of cookbooks.

**COCKTAILS.** Ever since America invented the cocktail, at the beginning of the nineteenth century, it has evolved: from sweet to dry; hot to icy; stirred to

Bartender making a Blue Blazer, a drink which has since given its name to a man's jacket. Wood engraving from Jerry Thomas, *Bartender's Guide* (New York, 1862). ROUGHWOOD COLLECTION.

shaken—a morning eye-opener to a conclusion to the day's activities.

Originally the name of a few specific drinks, the word “cocktail” soon became the generic name for almost any mixed drink. No one knows exactly why drinks came to be called cocktails, but there are many theories. In taverns, a cock is a tap; the dregs from the tap were called its tail, so some say the name signified the last dregs of a tavern tap. Others tell of a beautiful Revolutionary era barmaid who decorated drinks with cock's feathers and called them cocktails. The word might have originated with a medicinal chicken soup-like drink the English made from a cock boiled with ale, sack (wine from the Canary Islands), dates, and raisins. Thought to cure consumption, it was called cock-water or cock-ale. Another possibility is that since people generally started their day with a drink, the cocktail was named after the cock's wake-up call. Breakfast drinking was common, even among children, for centuries in Europe and continued in America from colonial times until the early mid-nineteenth century when the temperance movement gained strength. Beer soup was especially popular.

The most prosaic, and likely, theory is based on the fact that mixed, or nonthoroughbred, horses were called cocktails because their tails were clipped and stuck up like roosters' tails. Over time, the word “cocktail” came to stand for any mixture: mixed drinks, food mixtures such as fruit cocktails, and pharmaceutical combinations.

The first known definition of a cocktail appeared in an 1806 Hudson, New York, publication called the *Balance and Columbian Repository*. It defined a cocktail as “a stimulating liquor, composed of spirits of any kind, sugar, water, and bitters.” By the late twentieth century, a typical dictionary definition changed the meaning of the word to “any of various short mixed drinks, consisting typically of gin, whiskey, rum, vodka or brandy, with different admixtures, as vermouth, fruit juices or flavorings, sometimes sweetened.”

The definition changed because drinks changed. A late-nineteenth-century martini was made with equal parts gin and sweet vermouth, plus sugar syrup and orange bitters. A late-twentieth-century martini was made with vodka, not gin, and a few drops of dry, not sweet, vermouth, and no bitters and sugar syrup.

## The First Mixed Drinks

Originally, spirits were taken for medicinal purposes. Called *aqua vitae*, or the water of life, they were thought to improve health and promote longevity. Monks and apothecaries made potions from spirits mixed with herbs, spices, and fruits. They prescribed them for the pox and the plague, and even rubbed them on stiff joints. By the seventeenth century, Europeans were drinking the concoctions for pleasure as well as for pain relief.

When settlers came to North America, they brought a taste for spirited drinks with them. They made punch with rum, tea, sugar, water, and lemon juice. They drank flips made with beer, rum, molasses or sugar, and eggs or cream, all mixed together and heated with a red-hot poker. Possets combined hot milk and spirits. Slings were made of gin or other spirits, water, sugar, and lemon and served either hot or cold.

In 1862 preeminent bartender Jerry Thomas published *How to Mix Drinks, or The Bon-Vivant's Companion*, America's first mixed drink primer. Thomas wrote, "The 'Cocktail' is a modern invention, and is generally used on fishing and other sporting parties, although some *patients* [author's italics] insist that it is good in the morning as a tonic." He called just nine of his two hundred-plus recipes "cocktails," but within a few years the term became ubiquitous.

## The Party Begins

The Gilded Age was the golden era of the cocktail. At the turn of the twentieth century, affluent Americans frequented elegant hotels, bars, and restaurants; champagne cocktails were among their favorite drinks.

Talented bartenders knew how to make hundreds of cocktails—from the Adonis to the Zaza—and came up with new ones at will. They created and named drinks for regular patrons, news events, cities, and celebrities, and mixed them with great flair. Jerry Thomas was famous for his "Blue Blazer," a mixture of whiskey and boiling water, which he set ablaze and tossed back and forth between two silver-plated mugs. He said it looked like a "stream of liquid fire."

Cocktail shakers were invented in the late 1860s, and since ice was more available than it had been previously, the proper way to ice a drink became important. Drink manuals specified that some drinks be shaken, others mixed in a glass and stirred with a fork rather than a spoon.

In London, hotels and restaurants opened American bars and served American cocktails. They even hired American bartenders, especially after Prohibition went into effect in the United States in 1920.

America's party did not end with Prohibition—in fact, some might argue that drinking intensified during this era, with drunkenness becoming more commonplace—but it did go underground, and the cocktail

## A DRINK BY ANY OTHER NAME

The names of cocktails are often as inventive as the recipes. Here are a few intriguing examples.

- Cocktails named for animals: Bird, Chanticleer, Goat's Delight, Hop Frog, Hop Toad, Grasshopper, Prairie Hen, Mississippi Mule, Rattlesnake, Sherry Chicken, Yellow Parrot.
- Cocktails named for people: Bobby Burns, Charlie Lindbergh, Gene Tunney, Jack Kearns, Mamie Taylor, Mary Pickford, Phoebe Snow, Rhett Butler Slush, Rob Roy, Rudolph Nureyev, Tom and Jerry, Tom Collins, Will Rogers.
- Cocktails named for places: Big Apple, Brazil, Bronx, Brooklyn, Champs Elysées, Chicago, Cuba Libre, Fifth Avenue, Havana, Hawaiian, Manhattan, Martha's Vineyard, Richmond, Ward Eight.
- Cocktails named for occupations: Bishop, Chorus Lady, Commodore, Crook, Diplomat, Doctor G., Grenadier, Huntsman, Judge, Journalist, Kentucky Colonel, Merry Widow, President, Presidente Seco.
- Old school cocktails: Annapolis Fizz, Columbia, Cornell, Eton Blazer, Harvard, Old Etonian, Oxford Grad, Princeton, Yale.
- Royal cocktails: Count Stroganoff, Duchess, Duke, King Cole, Prince Edward, Prince's Smile, Queen, Queen Charlotte, Queen Elizabeth.
- Cocktail contradictions: Church Parade, Presbyterian, Prohibition, Puritan, Reform.

changed. Bartenders disguised the harsh taste of bootleg liquor by adding cream to drinks. Gin became the spirit of choice because it was easy to make faux gin by mixing juniper oil into alcohol. It was more difficult to replicate the taste of whiskey. Many people opted to drink in the privacy of their own homes, and cocktail sets—tray, shaker, and glasses—became popular wedding presents.

After Prohibition, which was repealed in 1933, most of the creamy cocktails disappeared, and trendsetters began ordering their martinis dry. However, in the 1933 "Repeal Edition" of the *Cocktail Book*, a dry martini was two-thirds gin, one-third French vermouth, and two dashes of bitters.

## Just the Basics

During World War II, the cocktail repertoire shrank. People turned to basic drinks such as highballs, martinis, and Manhattans. In the 1950s Americans frequented cocktail lounges, threw cocktail parties, and women wore

cocktail dresses. They ate bite-sized cocktail snacks and carried on brief, snappy cocktail-party conversations. Bartenders were not expected to know how to make hundreds of drinks, but they were expected to make ever-drier martinis.

Vodka, so little known in America that it was once sold as “white whiskey,” began its rise in popularity. Gradually, it took the place of gin in the standard martini and eventually became the best-selling spirit in America.

During the late 1960s and early 1970s, trendy young people drank white wine or smoked marijuana instead of drinking spirits. Cocktails were for old folks. Sales of brown liquors, such as whiskey, plummeted. However, cocktails began showing signs of life during the 1980s. The martini became hip again, and bartenders created dozens of variations on the theme. At the beginning of the twenty-first century, new cocktails—cosmopolitans, chocolate martinis, black icebergs—signal the beginning of yet another era in the evolution of the cocktail.

**CODEX ALIMENTARIUS.** Codex Alimentarius is a small global agency that establishes international standards for substances potentially harmful to human health and the environment—that is, food additives, chemicals, pesticides, and contaminants. Created jointly in 1963 by the World Health Organization (WHO), responsible for food safety and public health, and the Food and Agriculture Organization (FAO), responsible for food production, Codex is located in FAO headquarters in Rome. FAO is the dominant partner, contributes more than two-thirds of the cost of the organization, supervises the staff, and generally sets an agenda favorable to concerns of industrial agriculture.

Some 170 developed and developing countries are members of Codex. Their representatives meet as the Codex Commission every two years, alternately in Rome and Geneva, Switzerland (where WHO is headquartered), to review the status of standards being developed in some three dozen Codex committees, and to adopt or return standards recommended by those committees. Each committee is chaired by a nation that agrees to pay the committee's administrative and operational costs, an arrangement that makes a virtue out of the necessity of a small Codex budget. Not surprisingly, all major committees are headed by developed nations, with some countries chairing more than one committee. Codex members may self-select membership in committees, the choices being determined by national interest in specific standard issues and limited by national budgets for travel and staff. All substantive work on standards is done in Codex committees. The commission elects an executive committee and a chairperson every two years to supervise the work of a secretariat staff and to coordinate the work of the committees. Codex operates under consensus rules (that is, votes are rarely taken), a practice that avoids the impression that standards are based on political maneuvering for votes rather than on scientific research. Codex has voted on standards only six times in

its forty-year history, and only once prior to 1994. In each of those events, the tally was so close as to lead observers to conclude that no consensus exists on global standards. Codex has a small administrative staff of six people, does no research, and relies instead on the scientific capabilities of its member countries and on the advice of international scientific bodies.

Codex was established to provide a reliable standard-setting process to assist developing countries lacking the infrastructure to create domestic safeguards for food safety and health. Codex standards also offer developing countries the assurance of a floor for health and environmental standards on which to build export markets, primarily to developed countries. A recent study estimated that, on average, each developing country would need to spend \$150 million to achieve the internal capability of providing food safety and environmental standards. However, less than a fifth of developing-country members of Codex allocate staff or financial resources to participate regularly in Codex committees or in the development of a strategic Codex plan to accelerate adoption of standards. The Codex Executive Committee proposed a \$98 million fund to assist developing countries to comply with the accelerated adoption procedures, with the understanding that developed countries would pay for the fund, which would become available after 2003 if the Codex Commission were to approve the fast-tracking of standards and developed countries contribute the funds.

Until 1994, Codex provided standards that were global floors that countries could apply domestically to protect consumer health and the environment. Countries could set and enforce standards higher than those recommended by Codex. After 1994, with the creation of the World Trade Organization (WTO), Codex standards were transformed into global ceilings limiting the ability of individual nations to employ standards for health and environmental protection that exceed Codex levels. Countries may adopt higher domestic standards than those approved by Codex, but those standards are considered a trade violation when challenged in the WTO, where the measures for trade-rule violations are Codex standards. No country can be forced to drop more precautionary standards, but failure to do so will result in economic penalties being imposed by the WTO. However, neither the WTO nor other global agencies penalize countries that adopt standards less protective than those that Codex provides.

**COFFEE.** Coffee refers to both a plant and to the hot and cold beverages made from the pit or “bean” of its fruit. Coffee contains significant amounts (between 0.8 percent and 2.5 percent) of the stimulant alkaloid caffeine (trimethylxanthine) as well as protein and carbohydrates. The coffee shrub or bush grows as two species, *Coffea arabica* and *C. canephora*, and is indigenous to Africa, specifically to the Kaffa region of Ethiopia. The word “coffee” is derived from the Turkish word *kabveh*, which is rooted in the Arabic word *kabwah*, meaning wine, this indicating the use of the beverage as a replacement for alcoholic beverages that are forbidden under strict Muslim religious law.

The coffee plant is an evergreen with elliptical, dark shiny green leaves that yields a red husked berry containing a seed pit or “bean.” Coffee belongs to the Rubiaceae family and, depending on which of two species from which it is harvested, propagates differently. *Coffea arabica* is grown principally in Southeast Asia, Latin America, and the Caribbean. *Coffea canephora* (also known as *Coffea robusta*) is grown in Africa (mostly in the Congo), India, and Vietnam, which is its leading producer. The *arabica* is self-pollinating, while the *canephora* or *robusta* needs cross-pollination to fruit. After planting, the shrub requires four to five years of growth before it will fruit. When harvested, the ripe red husk is removed from the berry, and the fresh seed can be planted to generate seedlings or dried for planting at a later time. (It is this seed that is the coffee bean as it is commonly understood.)

Processing the beans requires two steps. In the first step, usually in the country of origin, the husk of the berry is left to ferment and soften, which facilitates the extraction of the seed or bean. The beans are then dried and shipped “green” or unroasted to a destination where they are roasted either for local consumption or for packaging and transshipping to other markets. The roasting process has a substantial effect on the color and flavor of the bean and the beverage it will produce. The darker the roast, the stronger the flavor. It is also the roasting process that eliminates water, making the bean more brittle and easier to grind.

*Coffea arabica* produces the “Arabica,” also known as “Brazilian,” varieties, which are often preferred for their balanced aroma and rich flavor. The best, rarest, and most sought after *arabica* types are harvested in Indonesia, Jamaica, Hawaii, and Colombia, where they are grown on small production farms at a relatively slow and steady growth rate, developing flavorful berries. (In this way they may be said to parallel wine production.) *Coffea canephora*, or *robusta*, tends to be strong and bitter. Because *Coffea canephora* can resist frost and disease and can sustain warmer climates and lower elevations, it experiences faster growth patterns and higher fruit yields. This generally results in beans that contain more caffeine than *arabica* types but that lack subtlety and flavor. The *canephora* bean is said by experts to be neutral by comparison to *arabica*.

SOURCE: International Coffee Organization

It is believed that the earliest producers of coffee, the Ethiopians, did not brew coffee as it is recognized in the twenty-first century from the roasted beans but made drinks from the bitter berries, combined the roasted beans with butter or animal fat (most likely that of mutton), or chewed roasted beans as a mild stimulant. Numerous tales on the subject of coffee and its discovery exist. One of the most persistent is of a ninth-century Ethiopian goat herder intrigued by his intoxicated, hyperactive flock. Having grown curious, he sampled berries his goats had been eating and felt similarly stimulated.

No extensive or significant use of the coffee crop has developed among Ethiopia's indigenous peoples, and it became an exotic crop for them, exported first to Yemen, then to other Arab nations. It is noteworthy that coffee production did not develop in Africa until the twentieth century and that consumption there is minor. (The berries are sometimes used to enhance teas, which are generally preferred as beverages there.)

A primitive approach to making the coffee beverage may have originated at the beginning of the eleventh century in Ethiopia, however, this was likely learned through Arab traders who ground roasted beans into a fine powder and stirred it into hot water. Most scholars believe the antecedents of modern brewed coffee drinks were developed in the late fourteenth or early fifteenth centuries in Yemen and accredit the processing of the beans—

roasting, grinding, and ultimately brewing the pungent hot drink—to a sheik of the Sufi order. Irrespective of the drink's origins, wild coffee plants may have been cultivated as early as the sixth century, but it was not until the fifteenth century that the coffee bush, *Coffea arabica*, is believed to have been domesticated, developed as an agricultural product, and spread throughout Muslim nations from Southwest Asia to Southeast Asia, including the Indonesian archipelago.

When first brought into widespread use, coffee was usually taken as a dark, bitter drink. Sugar was rarely used in the Arabian beverage, perhaps for fear that it would overstimulate the mind. The spice cardamom was often added to the brew for a naturally sweet flavor, and perhaps to counterbalance or mediate its bitter essence. Cardamom-flavored coffee is most commonly associated with the beverage known as Turkish coffee, as is the eleventh-century approach to boiling the grounds as a brewing technique. (Sugar is often added in this version as well.)

Historically coffee was the subject of frequent controversy and confusion, and its rise—much like tea—parallels the development of international trade and economic interdependencies. Coffee was perceived, for example, early in its development to have medicinal benefits, including as a curative for mange, sore eyes, drowsy, and gout. However, it was also feared that, when mixed with milk, coffee caused leprosy. Coffee was often

at the center of political turmoil, especially through the development of coffeehouses in the Ottoman Empire and throughout Europe, where people could congregate and discuss ideas in an atmosphere conducive to (literally) stimulated conversation. Coffeehouses were associated with the plotting of insurrection in the Ottoman Empire and of both the American and French Revolutions, for example.

Coffee is one of the most common delivery systems for drugs in the world. Its caffeine stimulates the brain, improving one's focus. It is also a diuretic, washing out the kidneys. When taken in large quantities, the stimulant causes irregular heartbeat, uncontrollable shaking, and dehydration. Despite—or because of—these characteristics, by the beginning of the sixteenth century coffee drinking was widespread in the Middle East. Its powerful physical effects, however, were such that some Muslim scholars interpreted it as being contradictory to the spirit of the Koran and tried to forbid it. Others opposed its banishment and ironically included the beverage in religious worship. (Records of the period indicate that coffee was drunk inside the Sacred Mosque in Mecca, in present-day Saudi Arabia.) Early accounts exist of coffee drinking, ostensibly for the purpose of staying awake to pray and chant, during the evenings of the one-month fasting of Ramadan.

Coffee is also associated with superstitions and rituals. For example, not unlike tea leaf reading by Chinese fortune tellers, Turkish fortune tellers use the finished cup of coffee—which contains both liquid and grounds—turning it onto the saucer until cool. The cup is then turned back up, and any coffee grounds remaining in the cup are “read” as a basis for predicting the future.

From roughly the fifteenth century to the eighteenth century, coffee trade was monopolized by the Yemenis. The English and the Dutch traded with the Arabs at the major trading port of Mocha in Yemen for nearly half a century before they found a way to break the Arab monopoly. Ultimately Dutch smugglers stole beans from Mocha, carrying them to colonial Java in Indonesia for propagation. Through the Dutch act of pilferage, Indonesian coffee plantations came to produce an *arabica* bean popularly known as “Java.” (Eventually this bean was described by connoisseurs as among the finest *arabica* available.) The Dutch also sent beans back to Amsterdam for propagation in greenhouses. In short order coffee propagation and drinking spread rapidly throughout the Western Hemisphere and the European colonies. In an act of repilferage, for example, the French king Louis XIV engineered the theft of plants from Amsterdam, and these plants eventually were responsible for the development of coffee plantations in French colonial Martinique. In 1723 the coffee business was born of a coffee bush originating in Martinique and eventually engendered a New World coffee industry that by the twentieth century was responsible for 90 percent of coffee production internationally.

The coffeehouse became a symbol of the Beat generation during the 1950s and early 1960s. The Gaslight Coffeehouse in New York's Greenwich Village was once a well-known setting for various bohemian movements. This 1959 photo shows poet Dick Woods sitting over coffee with Eddy Slaton. © BETTMANN/CORBIS.

The early to mid-seventeenth century saw the rapid spread of coffee consumption throughout Europe, especially northern Europe, resulting in a significant demand. The possibility of financial fortunes along with the possibilities of lucrative taxes and perceived medical benefits made for both free market and government-encouraged spread of cultivation in tropical and subtropical climates across the globe.

Cultivation spread throughout Southeast Asia, the Caribbean, Latin America, Africa, and Brazil. The first Brazilian coffee bush was planted in 1727, for example, and it was cultivated by slave labor. While the crop experienced a somewhat slow beginning there, by the end of the nineteenth century Brazil's coffee-growing industry was profitable. By the early twenty-first century Brazil was the world's largest coffee exporting nation with Vietnam running second.

Coffee and its patterns of consumption were historically linked to politics as well as perceived curative and stimulant benefits. Originally coffee was enjoyed almost exclusively in coffeehouses, which were founded as specialty shops for the purpose of selling coffee by enticing traders to try the new beverage. The first coffeehouse (or *café*) opened in Constantinople in 1555, and within a few years the city counted hundreds of such establishments. In rapid turn the coffeehouse became a place for socializing. Paralleling the social patterns of teahouses in China, coffeehouses became meeting places for casual conversation and business and political discussions, including revolutionary

In the Arab world, the coffee break is much more than a pause in the day's schedule; it is a period of intense conversation and male socialization. These men are talking business over their cup of coffee in the Gulf Hotel at Manama, Bahrain. © ADAM WOOLFIT/CORBIS.

strategies. The empire's rulers quickly became concerned with the popularity of such places, where discontented commoners and intellectuals alike could gather and political uprisings could be discussed. (Restaurants either did not exist or were forbidden.) Ottoman coffeehouse proprietors were subject to harsh punishments, including being sewn in a bag and thrown in the Bosphorus.

Political mechanisms proved inadequate to stem rising enthusiasm for coffee and coffeehouses, however. Great profit centers, coffeehouses were often built in extravagant styles, imparting a social caché to the beverage. Spread by war and commerce, coffeehouses opened in European capitals throughout the early to late seventeenth century, increasing the beverage's popularity and supporting demand.

While coffee was a sort of luxury beverage at first, by the eighteenth century even less-fortunate Europeans could enjoy it (or some adulterated version of it) through sales by street hawkers. Innkeepers also made it part of their family-style menus, and some food historians link the introduction of coffee to creating the sequencing of a meal. In the mid- to late eighteenth century North American colonials drank coffee increasingly as a sort of protest against high British taxes on tea. Free to trade after independence (1776), Americans imported coffee initially from Haiti and Martinique, then Portugal and Brazil. By the mid-nineteenth century Americans

consumed an average of over six pounds per capita annually. To a large extent the commercialization, mechanization, marketing, and democratization of coffee in North America evolved the beverage in modern times. The nineteenth century also saw the introduction of the drink in various styles, including Italian espresso (a concentrated one-ounce liquid), cappuccino (a "long" espresso with frothed milk), French *café au lait* or Spanish *café con leche* (strong coffee with plenty of hot milk), or iced coffee with or without milk. Other popular combinations are Irish coffee, which includes whiskey and Baileys Irish Cream, and Vietnamese or Thai coffees, in which sweet condensed milk is added.

Coffee can be "pure," using either the *arabica* or *robusta* bean, or it can be a blend of the two. One of the oldest blends simply combines various proportions of *robusta* and *arabica* beans, making the resulting item either more smooth or more bitter. Some of the more innovative blends include hazelnut and vanilla flavorings, these tied to the late twentieth-century, principally American interest in "gourmet" coffees. While for hundreds of years coffee consumers in Europe purchased a brewed cup of the beverage for quick consumption, in the United States green beans generally were sold in bulk for home roasting. This shift from public coffeehouse to domestic brewing had a profound effect on the industry and psychology of coffee consumption. The American develop-

ment essentially stripped coffee of its political import, making it a modern commodity.

In other North American developments, at the end of the American Civil War, San Francisco's Folger's Coffee company gave customers a choice, offering both traditional green coffee beans and the more efficient and time-saving roasted beans. A new industry was born, and the tendency toward efficiency and rapid brewing was exacerbated. The Maxwell House company soon followed in Folger's footsteps, and in 1901 the first Maxwell House "instant" coffee came to market. This instant coffee was made by extracting water from brewed coffee and freeze-drying the remains. Other innovations followed. Decaffeinated coffee, which has significantly reduced amounts of caffeine, was made by steaming unroasted beans or by using a solvent, usually chlorine, to remove the caffeine. Because this process also removes some of the flavor from the beans, the stronger *robusta* variety is usually employed for decaffeinated coffees.

While coffee was added to a pot of water and boiled to produce the earliest versions of the beverage, Arab producers eventually filtered the brew through herbs to hold back the sediment. In eighteenth-century France, coffee was filtered through muslin bags, an innovative but ultimately inadequate process. The expatriate American inventor Benjamin Thompson—also known as Count Rumford—developed the broadly successful metal "drip pot," and a number of other inventors developed variations on coffee-brewing devices, many of which have remained in use in the twenty-first century. In 1819, for example, the percolator was invented in which hot water rises through a tube and into an upper container and infuses coffee. The early twentieth century saw the advent of true coffee filtering devices, particularly through the development of paper filters by the German Melitta Bentz Company in 1908.

The espresso machine (from Italian *caffè espresso*, literally, "pressed-out coffee") is usually associated with Italy, but it was pioneered in the early nineteenth century in German and French machines that used steam to push steam through coffee grounds. The modern espresso machine, patented in Italy in early-twentieth-century Italy, was developed by Desidero Pavoni (who bought the rights to the espresso machine patent in 1905), and was dramatically improved in Italy after World War II. The hiss of the espresso machine was a common sound in the Italian *caffés* of San Francisco's North Beach and in New York City's Greenwich Village decades before espresso and cappuccino became fashionable around the 1980s.

The difference in machines and grounds is important in the outcome of any coffee brew. For example, the espresso machine uses twice the amount of coffee as a percolator, a much finer ground of coffee, and much less water (actually steam), resulting in a dark, strong, bitter extraction. Different grinds exist for different styles of brewing. Coarse grounds are used to make filtered coffee,

Like tea, coffee evolved its own distinctive implements in the form of differently shaped cups, serving pots, and table accoutrements. This "Dragon Coffee Service" manufactured by the Komilov Brothers factory in St. Petersburg, Russia, between 1840 and 1860, transforms the traditional Russian tea service into a porcelain fantasy. © THE STATE RUSSIAN MUSEUM/CORBIS.

fee, fine grounds are used to make Italian espresso, and even finer grounds resembling the consistency of flour are used to make boiled Turkish coffee.

Harvested, roasted, traded worldwide, and consumed by people from different walks of life, coffee has created significant social crossroads for centuries. Once a luxurious beverage, coffee is enjoyed internationally by a diverse populace. Most often a morning beverage, its popularity has soared as both an afternoon and an after-dinner beverage. Variations abound. Aside from flavored and decaffeinated coffees, bottled coffees, coffee sodas, and other drinks are available.

Embracing this trend, and operating over 5,500 stores internationally (over four thousand in the United States alone), Starbucks is the leading coffeehouse chain of the twenty-first century. It sells coffees with multiple options (would you like a slice of banana nut loaf with your iced, decaf mocha java?) at the elevated average price of \$3.50 per cup in a lounge setting, and has pastries (and sometimes, sandwiches) available for purchase. This creates a comfortable atmosphere for conversation and reading, without any pressure to make a purchase and leave. Thus, since the early 1990s Starbucks has created a coffeehouse culture for the masses. With its appeal extending from corporate executives to students and housewives, it has brought the former aristocratic atmosphere into the mainstream. In this way it typifies the late-twentieth-, early-twenty-first-century "mass-class" and "leisure-time entertainment" marketing strategies. The success of Starbucks is also bolstered by its ability to extend the brand by selling T-shirts, travel mugs, and other coffee-related accessories in its stores. Starbucks also sells coffee beans and ice cream.

Coffee is not only a modern beverage but also an ingredient in desserts, including coffee ice creams, coffee gelati, and coffee-flavored cakes. Variations include the American “chimney sweep” recipe, in which vanilla ice cream is topped with powdered coffee and drizzled with a shot of whiskey. Italian tiramisu has lady fingers soaked in espresso coffee and set in a whipped mascarpone cream. In addition, an American classic dish called “Black-eyed steak” employs coffee to deglaze a cast-iron pan in which a slice of salt-cured Virginia Smithfield ham has been pan-fried; the bitter and salty *jus* is poured over the meat prior to serving.

**COLORING, FOOD.** Humans have always used the color of a food to form judgments about its desirability. The act of eating (and deciding what to eat) is a multi-sensory experience, synthesizing perceptions of sight,

taste, smell, and touch. Color provides visual information about a food’s quality and condition, and influences the perception of its flavor.

In nature, color is determined by a food’s inherent qualities, indicating types of flavor, and degrees of sweetness, ripeness, or decay. However, humans have contrived to add or change the natural color in foods from very early times and for a variety of reasons—for aesthetic purposes, to increase appetite appeal, for symbolic effect, to make a less desirable food seem more desirable, and to mask defects.

From ancient times, wide varieties of food colorants were derived from natural sources—plant, animal, or mineral. This changed in the middle of the nineteenth century with the discovery of synthetic dyes that soon found their way into food. These synthetics were, in general, less expensive as well as more stable, controllable, and intense in hue than natural color sources. Since that time, the safety and acceptable use of food colorants, both natural and synthetic, remain controversial topics, eliciting debate, continual scientific study, and periodic legislative action.

#### History of Coloring in Food

There is ample evidence that early civilizations introduced color into their food. Ancient Egyptians colored food yellow with saffron, and saffron is mentioned in Homer’s *Iliad*, dating from 700 B.C.E. Pliny the Elder relates that wines were artificially colored in 400 B.C.E. Wealthy Romans ate white bread that had been whitened by adding alum to the flour.

In the great houses of medieval Europe, cooks employed plant extracts of many hues. Along with the period’s painting and stained glass, the cuisine of the late Gothic period was informed by rich and ornate color. Parti-colored dishes, jewel-toned cordials, and shimmering jellies were colored red, purple, blue, green, and yellow. Saffron had migrated from Persia as far as England by the mid-fourteenth century, and indigo, turnsole, alkanet (borage root), red saunders (a powdered wood), marigold, turmeric, safflower, parsley, spinach, fruits, and flower petal extracts commonly colored the foods of the wealthy.

In the early Renaissance (1470–1530), a common belief in Europe, based on Arabic ideas, was that color in food not only indicated nutritional value, but also inherent medicinal power connected to spiritual, celestial substances. Eating sweet red grapes produced full rich blood, black food like pepper or fungi induced melancholy, and coloring foods golden promoted divine solar healing.

In the sixteenth century the New World food colorants annatto, paprika, brazilwood, and cochineal arrived in Europe. In Mexico in 1518 Hernando Cortés observed the Aztecs cultivating the tiny cochineal insects (*Dactylopus coccus costa*) that fed on red cactus berries. These insects were gathered by hand and ground into pigment, requiring 70,000 carcasses to make a pound. By

TABLE 1

Naturally occurring colorants			
Substance	Colors	Sources	Used in
Anthocyanins	orange-red to red to blue	berries, grapes, apples, roses, hibiscus, red cabbage, sweet potato	candy, fruit beverages, ice cream, yogurt, jams
Betacyanins	red	red beets, red chard, cactus fruit, bougainvillea	candy, yogurt, ice cream, salad dressing, cake mixes
Caramel	beige to brown	heated sugars	baked goods, gravies, vinegars, syrups, colas, seasonings, sauces
Carmine	red	cochineal insects	candy, dairy products, drinks, fruit fillings, surimi
Carotenoids	yellow to orange to red	saffron, tomatoes, paprika, corn, butter, palm oil, red salmon, marigolds, marine algae, carrots, annatto	meat products, cheese, butter, spice mixes, salad dressings
Chlorophylls	green to olive green	green plant leaves	green pasta, dehydrated spinach
Riboflavin	yellow	vegetable leaves, milk, eggs, organ meats, malt	flour, bread, pastries, cereals, dietary products
Turmeric	yellow	<i>Curcuma longa</i> rhizome	pickles, mustard, spices, margarine, ice cream, cheese, baked goods, soups, cooking oil, salad dressings

1600 approximately 500,000 pounds of cochineal were shipped annually to Spain.

It was common during the eighteenth and nineteenth centuries to employ food colorants to disguise inferior products, and the colorants used were frequently harmful (although natural) substances. In 1820 Frederick Accum described flour whitened with alum, pickles colored green with copper sulphate, and cheeses tinted with red lead and red mercuric sulfide. By the mid-nineteenth century, black lead, Prussian blue, lead chromate, copper carbonate, vermilion, and copper arsenite were also used to color food.

The British chemist Sir William Henry Perkin created the first synthetic dye, mauveine, in 1856 by oxidizing aniline. By the end of the century, eighty synthetic

dyes colored foods, and coal tar derivatives were the principle source of synthesized dyes. Americans and Europeans were consuming varieties of unregulated, artificially colored food, including jellies, butter, cheese, ice cream, sausage, pasta, and wine.

### Food Coloring Regulation

Government attempts to regulate coloring agents in food have had a long history. There was a 1396 edict in Paris against coloring butter. In 1574 French authorities in Bourges prohibited the use of color to simulate eggs in pastries, and Amsterdam forbade annatto for coloring butter in 1641. Denmark listed colors permitted for food coloring in 1836, and Germany's Color Act of 1887 prohibited harmful colors in food. A report to the British Medical Association in Toronto in 1884 resulted in the Adulteration Act, the first list of prohibited food additives. Australia passed the Pure Food Act in 1905.

The United States Food and Drug Act of 1906 restricted synthetic food colors to those that could be tested as safe. Of the eighty colors in use, only seven were approved as certified colors. In 1938 the Food, Drug, and Cosmetics (FD&C) Act approved fifteen dyes for use in food, drugs, and cosmetics and assigned color numbers instead of their common names (thus, amaranth became Red No. 2).

Government and consumers' concerns regarding food additives intensified in the 1950s with new scientific findings. In 1960 the U.S. Congress passed the Color Additives Amendment to the FD&C Act, which placed the burden of establishing safety on the food manufacturing industry and created a new category, "color additives exempt from certification." This includes both "natural colors" and "nature-identical" colors (those synthetically made but chemically identical to natural colors, like beta-carotene and canthaxanthin). The Delaney Clause prohibited any color additive that could be shown to induce cancer in humans or animals.

Since the 1970s the inclusion of colorants in food has received considerable scrutiny based primarily on concerns regarding the carcinogenic properties of colorants. In 1992 a U.S. court decision interpreted the Delaney Clause to mean that zero levels of carcinogens are permissible. With further research findings, certified colors continue to be delisted.

In response to increased consumer perception that natural colorants are safer, manufacturers have moved toward more natural and less synthetic colorants in food. However, the term "natural," as it pertains to colors, has never been legally defined and has no universally accepted definition. In addition, a small percentage of the population demonstrates sensitivity or allergic reactions to some natural colorants such as cochineal. Currently, consumer groups advocate the minimized use of food colorants, as well as a detailed listing of specific colorants on food labels.

**COLUMBIAN EXCHANGE.** The title of this article refers to the interchange of plants and food products that took place between America and Europe after Columbus's voyages to the New World. Although the exchange was carried out in both directions, the article places greater emphasis upon the transfer of American plants and food products to Europe than in the other direction. European products that brought about significant changes in New World diets include wheat; meat and meat products such as milk, cheese and eggs; sugar; citrus fruits; onions; garlic; and certain spices such as parsley, coriander, oregano, cinnamon, and cloves.

Among the products that arrived in Europe after the discovery of the Americas were many plants native to the New World and unknown to Europeans. Some plants were transported intentionally, perhaps by a returning Spaniard who had become accustomed to the exotic fla-

vors of America; others traveled uninvited, hidden in the nooks and crannies of ships or mixed with the ballast that Spanish ships carried on their return trips to the Old World.

Over the years, the seeds and plants were scattered throughout the nearby hills of the Mediterranean Basin by the wind, water currents, or birds, or by humans themselves. Now, over 500 years after their introduction to the area, they form such an integral part of the landscape that this would be unrecognizable for any Roman citizens who came in search of their ancient environment.

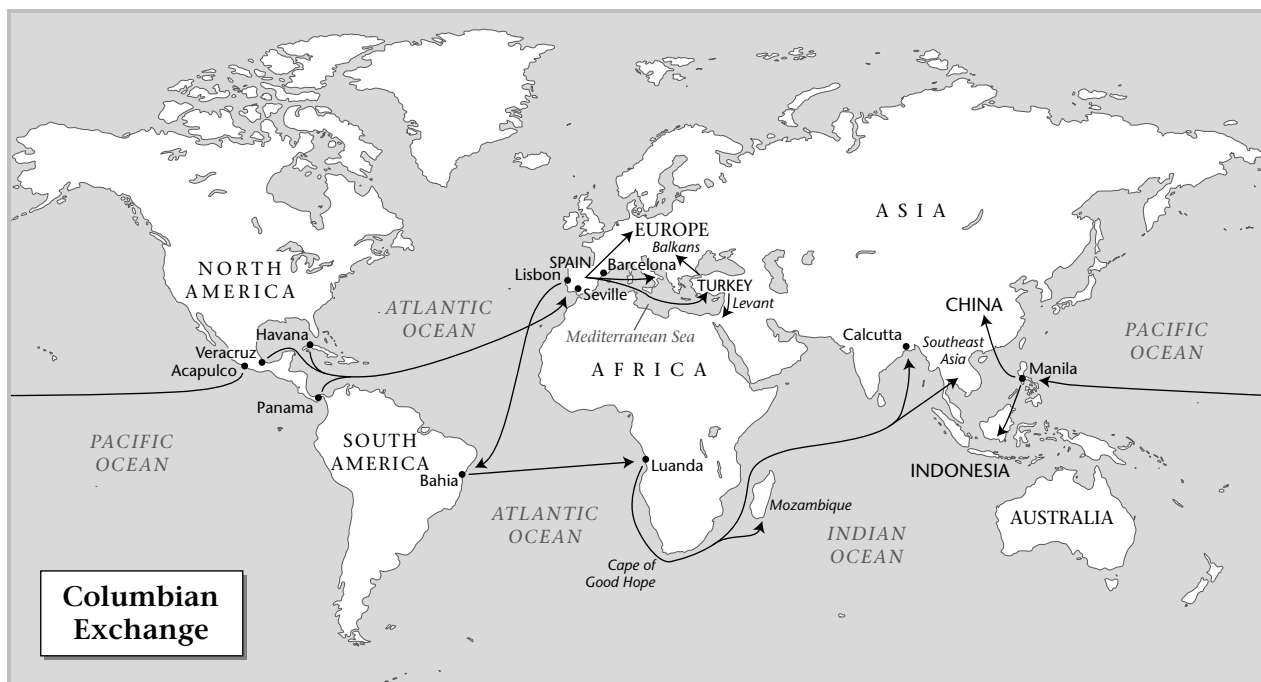

#### New World Plants in the Old World

American plants were not well received when they arrived in Europe. Some were the object of suspicion because of their similarity to a group of hallucinogenic plants already known and used by Europeans. Others had to undergo a genetic transformation before they could produce in the new climate and latitudes. American plants eventually became incorporated into the Mediterranean diet and now serve to identify it as readily as wheat, olives, and wine, traditional food plants of the area.

Spain became the route of dispersion for the new plants in Europe, since most of them initially arrived in the port of Seville. They extended along two distinct routes: one group was diffused toward the north of the continent, while others were found to adapt and prosper better in the south. The southern group first arrived in Italy, which should not be surprising since Spain controlled parts of Italy during the sixteenth century, and this facilitated the introduction of American plants to the area. The well-established trade routes set up by the Aragonese long before the sixteenth century were important factors in the dispersion of American products. The mild climate and loose soil that predominate in the Mediterranean helped make the area a favorable ecological niche for the adaptation and development of the new plants.

Maize and beans, subsistence crops throughout much of the Americas, prospered well in the Mediterranean Basin. Tomatoes and chili peppers adapted easily to the new atmosphere. Other crops that had little trouble in establishing themselves were several varieties of squash, sweet potatoes, the nopal, or prickly pear cactus, and the agave, or century plant. The potato, a plant that generated important changes in European social life, adapted better in the cold climates and high altitudes of Northern Europe, because of a greater similarity to their original habitat in the Andes Mountains of Bolivia and Peru.

Some of the plants rejected upon their arrival in Europe were the tomato, potato, and chili pepper. All are members of the *Solanaceae* plant family and had to confront the famous "curse of the nightshades" before being accepted in European diets. Europeans were already familiar with some poisonous members of this group of

plants such as mandrake, henbane, and belladonna, hallucinogenic plants used by witches and sorcerers of the time. They recognized these three plants as members of the same plant family by their leaves and flowers and were suspicious of them. In addition to being hallucinogenic and poisonous, the plants were believed to cause leprosy and syphilis. Soon they acquired fame as aphrodisiacs, although it is doubtful that this contributed to their rejection.

It was in the Mediterranean area where New World plants had their earliest acceptance. The Mediterranean Sea served as a background for the struggle between the Ottoman Turks and the Spanish Hapsburgs in the sixteenth century. These two empires played a dominant role in the region and were probably the most important distributors of American plants in Mediterranean countries.

The role played by the Turks is evident in the nomenclature of American plants in the sixteenth century. Maize appeared in European herbals with the name of Turkish grain, *blé de Turquie*, or *turkisher korn*. The chili pepper was called Turkish red pepper and squash was known as Turkish cucumber; even the American turkey received its well-known name in English at this time, when it was called the turkie-bird.

### A Historical Comparison of Plant Introductions

The arrival of American plants in the Mediterranean during the sixteenth century can be compared to a similar occurrence during Roman times. During the first years of the Empire, Romans followed a fairly simple diet. Their meals consisted mainly of boiled grains such as mil-

let, rye, and wheat, and of vegetables grown in the area. With the expansion of the Empire, trade and commerce began to flourish, and some Roman merchants began to introduce new food products from far-reaching corners of the Roman Empire. The best of the ancient world arrived at the tables of upper-class Romans. The variety of available food products increased considerably, and the new foods soon became a necessity in the Roman diet, giving rise to an elaborate and sophisticated cuisine.

It was not until the sixteenth century and the arrival of New World plants that this phenomenon was repeated in history. Plant specialists calculate that seventy-eight new plants, including fruit trees, vegetables, and spices, arrived in Italy during the centuries of the Roman Empire, while 127 arrived from America during just the first century following the discovery of the New World.

### Factors Determining the Acceptance of Plants

Some plants were easily accepted in the Mediterranean diet due to their similarity to other plants already known in the area. This was the case for the common bean (*Phaseolus vulgaris*) that showed a similarity with the fava bean (*Vicia faba*), known since Roman times and diffused throughout the area by Romans during their conquests.

The maize plant does not resemble other grains, although its preparation in the form of ground flour in breads and gruels gave it a certain similarity to them. Maize flour was combined with other ground cereals and used in the preparation of rustic breads, favored by the poor. It also came to substitute for millet in the preparation of Italian polenta, an ancient Roman dish that had been a mainstay of the poor for centuries.

While the foods of the New World radically changed the diet of the Old, so too did many Old World foods become staples of Native American diets. Here, a Kuna Indian woman is preparing to plant rice. She is holding the young seedlings in her hands. This picture was taken among the Kuna people at Comorcas de San Blas, Panama, in 1996. © DANNY LEHMAN/CORBIS.

The squash bore a resemblance to other cucurbits known to the Romans, although they belonged to other plant species. It received the name of *calabash* and a false identity as *zucco* from Syria. From this comes its present-day name, zucchini.

The chili pepper and the tomato arrived as new and strange plants, and people were suspicious of them. The fact that Europeans did not know how to prepare them and that they bore no resemblance to foods already in their diets made their acceptance more difficult. Chili peppers were too hot for the European palate, and they found the tomato difficult to prepare. It was too acrid to eat in its green stage, but when it ripened, it appeared to be spoiled, and when cooked, it disintegrated. Finally, they adopted the Aztec technique of grinding it into a purée. The tomato that arrived in the Mediterranean in the sixteenth century was not the bright red, smooth,

juicy fruit we know today, but rather a pale fruit with an acid flavor and unpleasant smell. The first illustrations in herbals show a small, ridged, hard fruit that does not look very appetizing. It was the caring hands of Italian gardeners that improved the American tomato and turned it into the vivid, plump, thin-skinned fruit we appreciate today. They also modified the chili pepper, turning it into a large fruit without the characteristic heat of the Mexican pepper. When transformed into a green pepper, it could be eaten as a vegetable, stuffed with meat or cheese, and it has found an important place in Mediterranean salads. Sweet potatoes and the prickly pear cactus adapted and grew wherever the climate and soil permitted them.

The Turks introduced American plants into the Balkans during their sixteenth century invasions of the region. Today the Hungarian chili pepper, called paprika, is one of the predominant flavors in Balkan cooking. Maize, squash, and tomatoes also play an important role in the cuisine.

### American Plants Incorporated into the European Diet

American plants arrived in Europe during the sixteenth century, but did not play a significant role in the European diet for two-hundred years. They became incorporated into the eighteenth-century diet, not as exotic or innovative dishes, but rather as additional ingredients in traditional foods already known and eaten by the masses. Cooks began adding maize and potatoes to popular soups and stews. American beans became a substitute for Roman fava beans in Spanish *fabada* (a bean stew from Asturias); white beans came to be used in *cassoulet* (a dish of southern France, made with beans and pork), as well as in Tuscan bean dishes. Sicilians discovered that tomato sauces were a good complement to pasta and pizzas and provided more color and flavor than the traditional butter or olive oil dressings. *Peperonata*, made with sautéed red and green peppers, occupies a place in all Mediterranean cuisines. The tomato and the chili pepper became a common ingredient in Greek dishes such as *moussaka*, made with lamb and eggplant, and in Hungarian dishes like chicken paprika or goulash.

Andalusian *gazpacho*, an ancient bread soup, possibly of Roman origin, suddenly took on a new presentation with tomatoes and green peppers. Valencian *paella* (a dish of rice, chicken, and seafood) and *bacalao* (a codfish casserole) soon included foods from America in their preparation. Innovative cooks created new dishes such as the *tortilla española*, a Spanish omelet cooked with potatoes, and “*pa amb tomàquet*,” thick Catalan bread slices smeared with tomatoes and olive oil. The Muslim tradition of filling vegetables with meat and sauce soon found new receptacles in American vegetables such as green peppers, tomatoes, and squash. Over the years, they learned to make Moroccan couscous with tomatoes, served with harissa sauce, made with mashed chili peppers, salt, and garlic.

The exchange of food plants from the New World to the Old moved in several directions. One was trans-Atlantic, the other was trans-Pacific. In these market baskets at Neiafu, Vava'U Island, Tonga Islands, New World manioc (center) is sold side by side with mangoes, fruits that came to the islands by way of Asia. © WOLFGANG KAEHLER/CORBIS.

## Conclusion

After an uncertain beginning upon their arrival in Europe, American plants revolutionized European diets as they slowly began replacing traditional ingredients and became staples in the basic diets of the area. They provided a more nutritional diet and helped put an end to the chronic famines that had affected Europe since the Middle Ages. Two New World plants, maize and potatoes, are considered among the four most important subsistence plants of the world and are believed to have played a role in the population explosion that began in the middle of the eighteenth century.

Maize quickly became a mainstay in the Venetian and Roman diets. It was easy to grow and so productive that many country people began living on a diet made up almost exclusively of maize products. Maize contains an incomplete protein and lacks tryptophan, a precursor of niacin, which helps the body synthesize vitamins. Without this amino acid, the body cannot absorb vitamins and thus produces a nutritional deficiency called pellagra, which affects the digestive and nervous systems as well as the skin. In extreme cases, it can be fatal. No Mediterranean country was saved from this terrible disease. It was not abolished completely in Italy until after the Second World War, when the diet and living conditions improved in that country. Potatoes were accepted in the diet in places like seventeenth-century Ireland, where the people were undergoing a severe food crisis; two centuries later, they were the cause of Ireland's "great

hunger" of the nineteenth century when the loss of the potato crop in consecutive years left people with nothing to eat.

**COMBINATION OF PROTEINS.** A thousand years ago, the Chinese poet Wu Tzu-mu listed the “seven necessities” of life that are still memorized by every Chinese schoolchild: firewood, rice, soy sauce, sesame oil, salt, vinegar, and tea. The list does not include meat. Now as then, we place great value on animal flesh as a food source, but depend on plants. Protein complementarity—or combining certain vegetable foods to achieve complete protein—solves a singular problem with that dependence.

Plant protein is an incomplete source of protein. Protein is built of amino acids, and of the twenty-two found in nature, our bodies can synthesize all but eight. These are termed “essential,” and must be found in the diet. Nearly all plants, however, are deficient in the essential amino acid methionine; only soybeans (*Glycine max*) and some seeds and nuts, especially the Mongongo (*Riciodendron rautanenii*) and sesame seeds (*Sesamum indicum*), can provide over 50 percent of our daily need. Legumes and pulses, such as peanuts (*Arachis hypogaea*), lentils (*Lens esculenta*), chickpeas (*Cicer arietinum*), and lima beans (*Phaseolus lunatus*), typically contain about half as much protein by weight as meat, and are good sources of lysine, but lack methionine. Many vegetables such as the squashes (*Cucurbita maxima*, *pepo*), cauliflower (*Brassica oleracea*), and runner or green beans (*Phaseolus coccineus*) have small amounts of protein, typically 1 to 2 percent by weight, but reasonably balanced amino acids.

Many populations, however, must find their protein in the same starchy carbohydrates that provide their calories. Corn (*Zea mays*), about 3 to 4 percent protein by weight, lacks methionine, lysine, and tryptophan, and is overrich in leucine. Rice (*Oryza sativa*, *typ*), also limited in methionine and lysine, has less total protein than corn by weight. However, its even amino acid profile gives rice greater bioavailability (how many of the amino acids our bodies can utilize). Whole wheat (*Triticum aestivum*) has four times more protein than corn or rice, but has low amounts of methionine, lysine, and tyrosine. Some tubers such as potatoes (*Solanum tuberosum*) have superior amino acid profiles to cereals, while others such as the yams (genus *Dioscorea*) and cassavas (genus *Manihot*) offer only about 1½ percent protein by wet weight.

Plants, moreover, contain tannins, phytates, and other indigestible fibers that bind with amino acids, reducing gut absorption and increasing fecal transit rates. Cereal protein digestibility, for instance, depends on whether one eats only the endosperm, source of most amino acids, or includes the fibrous pericarp.

Taking digestibility into account, we can calculate the utility of plant proteins relative to a benchmark—egg white. Soybeans, with a score of 99, are more bioavailable than beef, while peas and beans have scores between 60 and 75, nuts fall to the thirties, and most cereals are in the 20 to 30 range. Culturally important foods such as plantain (*Musa* spp), yams, and cassava (manioc) begin with modest total protein, contain high fiber, and thus end up with very low protein scores.

### Mixing Plant Proteins

With ingenuity, such shortfalls can be met by mixing amino acids from different plant foods. This has become known as protein complementarity. The best-understood example comes from Latin America’s menu. Squashes supply lysine, which corn lacks, and beans provide methionine. In sufficient quantity, the triad of squash, corn, and beans provides ample protein.

Moreover, as Solomon Katz has demonstrated, Latin American cultures typically soak their tortilla corn in lime. Besides enhancing availability of the B vitamin niacin, the alkali reaction reduces the amino acid availability of all amino acids except lysine, already deficient in corn. Paradoxically, this is useful. While total protein is reduced, amino acids are “leveled,” making a higher percentage of protein (approximately 8 percent by weight) complete. Finally, one of the amino acids reduced is leucine, an overabundance of which relative to lysine may be involved in the etiology of the disease pellagra. Thus lime soaking is a deceptively simple cultural practice that solves complex nutritional dilemmas.

Language itself attests to protein complementarity’s importance in East Asia. The Chinese *fan* literally translates as ‘grain’ (usually rice), but also signifies ‘food’. *Ts’ai* literally translates as ‘edible leaf and stem vegetable’, but also signifies ‘what goes over rice to complete the meal.’ One is reminded of the phrase from the Lord’s Prayer, “our daily bread,” that signifies all necessary food. Complementarity here rests on the soybean. Rice or wheat is mixed with dozens of soybean products, including curds (tofu), soy milk, boiled or fermented soybeans, and soy sauce. Soy sauce, in turn, typically is made with wheat flour, whose methionine enhances an already strong amino acid profile. Digestion of soy protein, moreover, is enhanced by traditional fermentation, accomplished in water containing dissolved calcium or magnesium. These inactivate the antagonists to trypsin, a digestive enzyme, found in soybeans. Finally, sesame oil, a rich source of methionine, has been a preferred cooking oil in China since the Sung dynasty. Not surprisingly, even in times of famine, straightforward protein malnutrition has been rare in East Asia.

As one proceeds inland west or north, pulses and legumes such as the red bean (*Vigna angularis*), broad bean (*Vicia faba*), the mung bean (*Vigna mungo*), the peanut, and the common pea (*Pisum sativum*) are mixed with cereals to aid complementarity. Fermented milk products such as yogurt become significant in Central Asia.

In the Middle East, South Asia, and Asia Minor, complementarity typically involves green vegetables, cheese, and lentils or peas with wheat. Wheat and pulses nicely complement each other’s lysine and methionine ratios; amino acid scores attain at least 85 percent of egg white. Protein malnutrition is again rare.

Comparatively protein-poor Oceanic foods such as breadfruit (*Artocarpus communis*), bananas (*Musa*), taro

(*Colocasia esculenta*), and yams tend to be served together, often with green vegetables. Fish or pork is typically added in small amounts. Except in mountainous areas of New Guinea, protein malnutrition is rare.

Both Southeast Asia and coastal West Africa illustrate a dilemma stemming from substitution of meat for plants. The dominant carbohydrate, rice, typically is topped by small amounts of fish, as a fermented paste (Southeast Asia), or dried fragments (West Africa); peanuts and green vegetables may also contribute to the sauce. With much rice and little fish, protein can become quite diluted. In northern Thailand, for instance, small children may not eat enough rice with fish paste to meet caloric needs. However balanced, the protein is broken down for energy. In Senegal, among the Wolof, dried fish tends to fragment during cooking and be diluted throughout the rice gruel. Adults consider this less tasty, and following their example, children may resist eating sufficient rice.

### Origins of Complementarity

The ingenuity and specificity of protein complementarity demands explanation. How did so many cultures independently discover protein mixing? Simple trial and error is unlikely, since protein undernutrition has ambiguous symptoms; even obvious malnutrition (kwashiorkor) has been variously attributed to supernatural intervention, inappropriate parental morals, or a failure of the child's will. On the other hand, dietary practices show good congruence with underlying biochemical advantages in growth and resistance to infection. Folk knowledge of these connections, however, remains poorly documented.

The origins of protein complementarity may be ecological. Optimization strategies must lead to a cost-benefit honing of the total menu available within any ecosystem. Nutritional benefits will be balanced against procurement costs. The !Kung San, for instance, select plant foods on the basis of abundance, ease of acquisition, and nutrient value. Elaborate taboos are reserved for meat, which costs more calories to obtain than it yields. Ultimately, any population whose long-term optimizations transgress nutritional requirements will suffer demographic collapse. We may, in other words, see close linkages between food choice and protein scores because cultures that ignored such an association are no longer extant.

Practices that enhance complementarity may operate through individual health-seeking behavior. Pairing introduced foods with familiar, liked components, such as mixing cereals with pulses, has been shown to facilitate acceptance in humans, but not in animals. The !Kung San typically equate nutrient value with tastiness, including texture, flavor, and smell. Such findings locate protein complementarity within what Pierre Bordieu terms "cultural habitas": a habitual, unremarked, individual practice that reflects group consensus about "how

things are done." This habitas serves to internalize biologically adaptive food choices.

Over evolutionary time spans, finally, some behaviors may have become encephalized, or incorporated into neural functioning. Monoamine neurotransmitters such as serotonin, dopamine, and norepinephrine are synthesized from two amino acids, tryptophan and tyrosine. Neuronal levels of these amino acids in plant-eating monkeys, for instance, vary systematically with intake when dietary protein is scant, but are insensitive to intakes above 10 percent. Reductions in neuronal level limit neurotransmitter synthesis in the hypothalamus, which in turn regulates appetite. The brain, then, may receive constant information about the amino acid balance of our diet, and mediate appetite to achieve optimal rates of utilization when protein is scarce. Individuals would not be conscious of such nutrient-seeking appetites. Rather, diets that yielded appropriate mixes would become associated with elevated affect; they would taste richer, or better satisfy cravings, thus conditioning individuals to seek those foods. Protein complementarity consequently appears to follow multiple adaptive paths, individual and social, using both biology and culture.

**COMFORT FOOD.** Comfort food is an increasingly prominent concept in the twenty-first century. Indeed, as a consequence of the term's increased use in the English language (likely a response to increasingly stressful living conditions), the editors of the *Oxford English Dictionary* added "comfort food" to its list of 1997 entries, defining it as "food that comforts or affords solace; hence any food (frequently with a high sugar or carbohydrate content) that is associated with childhood or with home cooking." That same year *Merriam-Webster's Collegiate Dictionary* added "comfort food" to the tenth edition, defining it as "food prepared in a traditional style having a usually nostalgic or sentimental appeal." Comfort food may be best thought of as any food consumed by individuals, often during periods of stress, that evokes positive emotions and is associated with significant social relationships.

Throughout history and across cultures, food arguably has always been associated with the provision of comfort. Indeed, from the moments following birth, the crying infant is immediately soothed with mother's milk or, in more modern times, infant formula. Only in the last decade of the twentieth century, however, did the notion of comfort food as a unique concept become part of the vernacular of everyday life. Julie L. Locher and colleagues have observed that "daily life in the modern world, with its concomitant stress, psychological discomfort, and personal dislocation, has given rise to the need for comfort foods, and in a capitalist economy, of course, manufacturers have fully exploited such a need" (2002, p. 5). Restaurateurs and cookbook writers have taken advantage of individuals' needs for comfort as well. Contemporary societies have witnessed a proliferation of restaurants, including high-end restaurants, that feature comfort food on their daily menus. Additionally, growing numbers of cookbooks are dedicated exclusively to recipes for comfort foods, and whole cookbooks focus entirely on single comfort foods, such as macaroni and cheese (Schwartz, 2001). The notion of comfort food appears regularly in popular magazines (aimed primarily at women), television, and literature. Heralding the rise in the popularity of comfort food, *Bon Appetit* devoted most of its February 1998 issue to comfort food.

Several researchers have either demonstrated or speculated that links exist between physical or psychological aspects associated with mood and the consumption of par-

ticular foods, especially those foods high in carbohydrates (both sugar and starch) and fat. The most conclusive and widespread evidence arising from this investigation is that foods high in carbohydrates increase the availability of tryptophan, which increases the level of serotonin in the brain and results in a better mood state. Another plausible biological explanation for the link between food and mood maintains that foods that taste good may promote the release of endogenous opioids and thereby alter one's mood state. These physical and psychological observations may help explain some of the food objects individuals consume to provide comfort but certainly not all foods. Further, they do not explain the diversity of food choices among individuals and groups or why people choose some foods and not others for comfort.

Some researchers have emphasized the social dimensions of comfort food, noting that comfort foods are those familiar to the individual, are associated with feelings of nostalgia, are usually convenient to prepare and consume, are often indulgent, and typically provide a sense of physical as well as emotional comfort. According to Brian Wansink and Cynthia Sangerman, the most commonly reported comfort foods consumed in the United States are potato chips, followed by ice cream, cookies, and candy (2000, p. 1). All of these investigators found gender differences in what individuals perceive as comfort foods. Men are more likely to prefer entire meals, while women are more likely to prefer sweets (including chocolate) and snack foods. Age differences were identified also. Younger people prefer sweets and snacks, while older people prefer hot foods like soup and mashed potatoes.

Comfort foods are consumed under different circumstances in individuals' lives. Both social and psychological research indicates that when persons are feeling either sad or lonely, they may be more likely to consume particular foods. Additionally, researchers have found that persons consume comfort food when they are feeling "jubilant," when they need an incentive to get through something particularly stressful, or when they wish to be rewarded for something they have accomplished. The emphasis in most writings on comfort foods, in both the popular press and the academic press, is on personal sources of distress that encourage consumption of comfort foods.

Comfort foods are consumed during periods of societal uncertainty and crises. For example, immediately following the 11 September 2001 terrorist attack on the World Trade Center, restaurateurs across the United States reported increased sales of comfort food items, such as soup, mashed potatoes, puddings, and macaroni and cheese (Thorn, 2001). A Nielsen survey of grocery stores reported a significant increase in the sales of both snack foods and instant potatoes ("Nation Turning to Comfort Food," 2001). These reports may help explain why the notion of comfort foods became so important at that particular time in history. Conditions of postmod-

ern societies present individuals with stressors that are often beyond their control. At the same time, societies have become consumer-oriented, and individuals have become more defined by the objects they consume. The consumption of particular food objects for comfort may be one of the primary ways individuals can maintain control. Thus, eating comfort foods may be a means of maintaining control over the self when all else seems out of control. In essence, comfort food provides individuals with a sense of security during troubling times by evoking emotions associated with safer and happier times.

**COMMODITY PRICE SUPPORTS.** Commodity price supports are statutory devices designed to enhance the net income of agricultural producers. These laws are called subsidies because they use the power and wealth of the state to "subsidize" producers by artificially supporting prices of agricultural commodities, reducing the cost of producing them, or, in some cases, providing direct cash payments to producers. In the United States, the core of statutory authority for price supports rests in Title 7 of the U.S. code and the Agricultural Act of 1949, as amended. These laws authorize loans that producers are not legally required to repay, open-market purchase of cranberries, and direct cash payments to dairy farmers under the Obey-Kohl Amendment to the 2001 Agri-

cultural Appropriations Bill. Most of these laws were enacted in the Depression era of the 1930s but have been modified and extended up to the present time. Price support programs started out with six "basic" commodities (four from the South: peanuts, cotton, tobacco, and rice, and two from the North: wheat and corn). There now are some two dozen commodities that receive price support benefits. Both the cost and the complexity of these laws have grown dramatically. Sometimes these programs have collided with each other (like in 1983 when a federal law to kill aging dairy cattle in a futile attempt to raise milk prices seriously depressed beef prices as an avalanche of dairy cow meat buried the beef market).

While price support laws are aimed at achieving income parity for farmers and ranchers, there are many other laws that affect agricultural prosperity. For example, the Conservation Reserve Program currently idles about 36 million acres of fragile cropland. While conservation and environmental concerns may be the prime objective of this program, a substantial side-effect is the income stability for crop producers that comes from idling that enormous acreage. This phenomenon is present in other USDA conservation programs such as wetlands and forestry.

Another important agricultural law that has a major impact on farm prices and income is P.L. 83-480, the "Food for Peace" program. Through the years this major trade law has funneled billions of agricultural commodities into developing foreign nations, thus boosting domestic prices.

Other laws that indirectly boost U.S. farm prices include: Farm Credit Programs by USDA such as FmHA (Farmers Home Administration) and crop insurance. Also helping farm prosperity are the banking services of the Farm Credit Administration.

At this point it should be noted that states use their "negative" pricing power to reduce farm prices and farm income. Examples range from price controls during World War II and Korea to embargoes by Presidents Nixon, Carter, and Bush. Even seemingly unrelated programs involving agricultural research, such as the use of genetically modified organisms (GMOs), affect farm prices. Tax policy by federal, state, and local governments can also play a major role in the economics of farm owners and operators.

One final thought: In ancient Athens, it is said that the people despaired over the high price of figs, so that Archon commissioned a bevy of "fig watchers" or sycophants to keep both fig exports and fig prices low. It was probably the first "cheap food policy," but governments have been struggling ever since to organize a price support system that will be fair to both producers and consumers.

**COMPOTE.** The word “compote” comes from *compositum*, the past participle of the Latin verb *componere* used as a noun. The basic culinary meaning refers to any preparation assembled from a variety of ingredients, with the added inference that this was done in a predetermined or formulaic arrangement. The English word “composition” also derives from this same root, and in both terms the aspects of visual appearance and texture play a key role. Roman cooks seem to have recognized a *compositum* when they saw one, but so few culinary texts have survived from Roman times that we seem to have only one recipe from Apicius as a reference point: *Rapae ut Diu Servuntur*, or turnips preserved in honey and vinegar with or without myrtle berries, mustard seeds and salt (Lib. I, xxiv; Milham, 1969). Significantly, Apicius did not use the term *compositum* anywhere in his surviving text.

It is not until the Middle Ages that the term *compositum* appears with any regularity, and it is clear from the medieval texts themselves that several distinctly different preparations went by the name of *compositum*. One of the oldest references, from the 1300s, was called a *confectio compositi* (Moulon, 1971) and consisted of parsley and celery root, cabbage, vinegar, pork, and other ingredients. It was a layered dish evidently baked in a deep earthenware pot and the prototype of a common one-pot dish known throughout southwest Germany, Alsace, and Switzerland as *Gumbis* (or some variation of that spelling).

In his *Theatrum Botanicum* (Basel, 1696) Swiss physician Theodore Zwinger described a common *Gumbis* made from pared turnips laid down in tubs with layers of barberries and sloes, then covered with spring water and salt. This sweet-and-salty vegetable preserve was eaten as a dessert, while the liquid was used in home remedies. This is not a cooked dish, yet it does follow in the tradition of Apicius and thus must be a recipe of considerable age. It is echoed in an eighteenth-century American recipe for preserving stone fruit in honey and spring water.

Hans Wiswe (1970) published a number of medieval German recipes for *compositum* and noted that they fell into three groups: First, a type of preserve employing fruits or vegetables, or a mixture of both, together with honey. In Renaissance cookery this evolved into fruit stewed in honey or in a sugar syrup. Second, layered sauerkraut mixtures, such as the addition of root parsley (Hamburg parsley) and turnips or some other root vegetable, even, perhaps, horseradish. Third, food mixtures prepared in deep earthenware baking pans and arranged in layers, invariably with shredded cabbage, shredded turnips, sauerkraut, fruit, and quite often small pieces of meat. Thus a recipe made primarily with sliced apples becomes *poma composta* or *Gumbis äpfel* (apple Gumbis). The traditional *Gumbistöpfel* of Canton Aargau in Switzerland employs dried pears. Many of the recipes are highly regionalized and thus point to the great age of this concept.

Such medieval layered mixtures continued to be made in North America by German-speaking settlers

from Switzerland, Alsace, and southwest Germany. These fruit-cabbage-and-meat mixtures are discussed by Weaver (1993), who pointed out that they represent a type of one-pot meal once common throughout the Pennsylvania Dutch settlement area. Published recipes have also emerged in a number of nineteenth century sources, such as George Girardey's *Höchst nützliches Handbuch über Kochkunst* (The Handbook of the Art of Cooking; Cincinnati, 1842). It is the sweet *compositum*, however, which has gained the most widespread acceptance in European cookery today. It is almost universally referred to by its French name: compote.

### Sweet Compotes

The sweet *compositum* is doubtless itself of great age and probably draws upon antecedents in the eastern Mediterranean. A preparation known as *mabés* (pronounced mah-CHESS) made in rural Cyprus points toward the antiquity of this concept. Grapes are partially dried in the sun, then packed tightly into a *goumni* (a type of small earthenware jar holding 5 to 6 liters), closed tightly, and allowed to ferment for two to three months. The result is a thick, syrupy, alcoholic delicacy which is eaten for dessert with a spoon. Slight fermentation appears to be one of the defining elements in this type of preparation and thus would explain why “compost,” the old English term for it, eventually migrated in meaning to the more narrow sense of fermenting garden debris, as in the term “compost heap.”

Hieatt and Butler (1985) published a reference to *datys in compaste*, mentioned on a medieval English menu,

### GOOSEBERRY COMPOTE WITH RED CURRANT JUICE

This German recipe is structured in such a way that 1 pound of any tart fruit or berries may be substituted for the gooseberries.

Yield: Serves 4 persons

1 pound (500g) ripe gooseberries

1/2 cup (125ml) red currant juice

3 tablespoons (45g) sugar or to taste

Pick the gooseberries of their stems and tails. Put them into a sieve and blanch in boiling water for a few seconds. Then place them in a stewpan with the currant juice and sugar and cook gently until they are soft. Serve warm or cold with vanilla ice cream or with crème fraîche.

SOURCE: Adapted and translated from Hedwig Heyl, *A B C der Küche* (Berlin, 1938), p. 317.

and suggested this might be preserved dates, describing it as something akin to chutney. It is difficult to know exactly what was meant, since there are a variety of ways the dates could have been preserved—even in simple syrup, but in all likelihood, the date mixture was probably more like *mabés*, since this was a common export item from the Latin kingdoms in the eastern Mediterranean. Whatever the case, two important points emerge: the use of the term “compote” in English and a direct association with something that is sweet and sticky.

A great deal has been written on the subject of the Arabic invention or perfection of this type of confectionery, especially where cane sugar was employed. Doubtless the technological trail can be traced to Persia or even India, where sugarcane was known and used for thousands of years. If there was a more westerly epicenter for sugar confectionery, then it was most certainly Syria, for the Syrians held a monopoly on sugar technology for a very long time during the Middle Ages. Even in the Latin kingdoms established in that region during the Crusades, Syrian Christians remained in charge of the sugar mills and confection shops. Let it be said, however, that before the arrival of sugar and its commercialization in the eastern Mediterranean, *epsima* (grape syrup), carob syrup, pomegranate syrup, date syrup, and, of course, honey played a significant role in the preparation of sweet fruit dishes. These preparations were primarily medical in nature but also pleasant-tasting.

### The Move to the West

Wet, sticky fruits were exported to the West as luxury medicines, but as sugar became more available to Europeans, the art of making these medicines quickly spread as well, especially among druggists. These foods were often eaten at the end of the medieval meal to help rebalance the bodily humors, but in time became associated more and more with the banqueting course, as the dessert course was eventually called during the Renaissance. Cookbooks of that period generally lump the compotes together with cakes and other desserts, and that is where the preparation has remained on the menu down to the present day.

Culturally, fruits stewed in sugar play a far more significant role in the cuisine of Scandinavia, Russia, German-speaking Europe, and the Balkans than they do in modern American cookery. In those countries, the compote is a popular warm-weather food, almost a midsummer institution, whereas in the eastern Mediterranean, fruits prepared in sticky syrup are generally eaten as a delicacy served with very strong coffee.

**CONDIMENTS.** The term “condiment” originally meant seasoned, pickled, or preserved foods in Latin. Today, the word is broadly applied to a variety of foods, including spices, herbs, sauces, seasonings, flavorings, colorings, and even beverages, such as tea, coffee, and alcoholic drinks. A more narrow definition is that a condiment is a substance added to other foods for the purpose of giving a strong flavor or relish. Condiments usually appear on the table and are intended for individual use by the diner.

Condiments fall into five nonexclusive categories. The first is salt, the earliest and most important condiment employed by humans. In addition to its ubiquitous presence on tables around the world, salt is often a constituent ingredient in many other condiments. It is employed on a wide range of foods, including vegetables, meats, fish, and poultry. Salt is also occasionally shaken on beer and sprinkled on watermelons. Salt is a major preservative and today is commonly found in most processed foods.

The second most common condiment is sugar or other sweeteners, such as honey or maple syrup. Sugar and honey are used directly in everything from bitter beverages, such as tea, coffee, and chocolate, to a topping for breakfast cereals. Sugar and honey are also employed in making other condiments such as jams, jellies, preserves, and marmalades, and are used extensively on bread, rolls, scones, and in pastries. Maple syrup is commonly used on pancakes.

A third category of condiments is pickled foods, which date back to the ancient world in Europe as well as Asia. Common pickled foods used as condiments today include ginger (Japan), chutney (South Asia), and

cucumbers (dill, butter, and gherkins). Almost all vegetables have been pickled and used as condiments in some form. They are served whole, in slices, or diced in a relish. Sliced and diced pickles are frequently used on sandwiches.

### Spicy and Hot Condiments

A fourth condiment category are those spicy or hot foods, such as black pepper, chili pepper, mustard, garlic, horseradish, and onions. A product of Asia, black pepper (*Piper nigrum*) is commonly served from shakers throughout the Western world in a dried state and is usually ground into coarse or fine state before consumption. Like salt, pepper is used in savory dishes. It is also a base ingredient in some pepper sauces. Chili pepper (*Capsicum*), a product of the Americas, is employed in dried form on diverse foods.

Fresh chopped chili peppers are also the base ingredient in a number of other condiments, including salsa. In pre-Columbian times, the Aztecs employed a number of sauces based on chili peppers along with tomatoes and ground pumpkin seeds. After the Spanish Conquest in 1521, fusion foods developed including *salsas*, which combined salt with ground tomatoes and chili peppers from the New World and vinegar from the Old World.

Tabasco sauce was an early American condiment based on chili pepper and vinegar. As Mexican cookery became an important food for mainstream Americans in the latter part of the twentieth century, *salsas* became an important part of cookery in the United States. The fresh salsa market exploded during the 1980s and continued to increase during the following decade. By the 1990s, salsa outsold ketchup.

Salsa is also used in making other condiments, such as guacamole, a combination of mashed avocados, salsa, onions, garlic, and other ingredients. Today, guacamole is served in Mexican restaurants and used as a dip for tortilla chips. Numerous other condiments serve as dips for potato and corn chips.

### Mustard and Horseradish

In ancient Roman times, mustard was made from seeds of a variety of plants in the genus *Brassica*. The word originated in Latin and meant the “must” of new wine, which suggests that mustard seeds were combined with wine or vinegar. At an early date, mustard was disseminated throughout China, where it also became an important condiment in Chinese cookery.

The use of mustard survived the Middle Ages in Europe and was commonly employed in French and British cookery. Special dishes were developed for mustard’s use as a table condiment. A major area of mustard production in France was the region around Dijon. Powdered mustard was commercialized in England and was produced in the United States by the mid-eighteenth century. The R. T. French Company began bottling a mild

mustard in the United States about 1900. It was soon served on hot dogs and later hamburgers.

Horseradish (*Armoracia rusticana*), a product of western Asia, is a relatively recent addition to Western cookery. Pickled and ground, it is a highly pungent condiment used particularly with roast beef in England and other meats throughout Europe. In Japan, wasabi (*Eutrema wasabi*) serves a similar function for sushi.

### Other Compound Sauces

The fifth and final condiment category is compound sauces, including ketchup, Worcestershire sauce, fish sauces, soy sauce, salad dressings, curries, and barbecue sauces. The earliest known compound sauces were made of fish. In widely separated regions, such as in the ancient Mediterranean and Southeast Asia, preservation of fish in a liquid form evolved.

In the ancient Mediterranean world, fish sauce called *garum* was initially made in the Greek communities along the Black Sea coast. It was heartily adopted by the Romans, who employed fish sauces lavishly on many dishes to enhance flavor. It was used as a cooking ingredient as well as a dip for fish and other foods at the table.

Fermented condiments were also developed in ancient China and Southeast Asia, where fish and other fermented sauces played significant culinary roles. By the seventeenth century, diverse sauces were manufactured throughout East and Southeast Asia. Today, China, India, and Japan produce small quantities of fermented fish sauces, but Southeast Asia remains the center of production and consumption. Beginning in the early twentieth century, authorities set standards for fermented fish sauce in French Indochina. These and subsequent standards formed the basis for commercial production. Fermented fish sauces, such as *nam pla* in Thailand, *nuoc mam* in Vietnam, *tuk trey* in Cambodia, *ngan-pye-ye* in Myanmar, *budu* in Malaysia, *patis* in the Philippines, and *nam pa* in Laos, continue to be very popular. These sauces are more than just flavor enhancers: they contain high levels of protein and other nutrients.

Another important Asian condiment was soy sauce. Soybeans had been converted into a sauce at least since 200 B.C.E. in China. It spread quickly throughout East and Southeast Asia. Although soy sauce production is believed to have started in China, eventually Japan became a major producer. Its popularity was spread by Buddhists, who used it as an alternative to fish sauce.

### Ketchup

Another fermented East Asian and Southeast Asian sauce was *kê-tsiap*, which in the Amoy dialect of Chinese meant “the brine of pickled fish.” The British encountered these sauces in Indonesia in the late seventeenth century. In the late seventeenth and early eighteenth centuries, *ketchup* simply meant sauce, and usually referred to fermented black soybeans with a roasted cassava flour. The English

word “ketchup” derived from the Indonesian word *kecap*. Anchovies were an important ingredient in early English ketchups. Although anchovies are no longer an ingredient in ketchup, anchovies were incorporated into several commercial brand-name sauces and relishes that were created during the nineteenth century, including Harvey’s Sauce, Gentleman’s Relish, and Lea & Perrins Worcestershire Sauce, which still feature anchovies as ingredients today.

Like fish sauces, ketchups were used in cooking to produce particular colors, consistencies, or tastes and were used as condiments on fish, fowl, and meats. Many types of ketchup were based on other products. Among the more important were walnut, mushroom, and later tomato ketchup, which became particularly popular in the United States. As the price for tomato ketchup decreased and became accessible to all Americans at the end of the nineteenth century, tomato ketchup became America’s national condiment and other types of ketchup almost disappeared. Tomato ketchup has expanded beyond the English-speaking countries and today is manufactured in more than seventy countries and is consumed to some degree in nearly every country.

Tomato ketchup has also inspired other condiments. In the Philippines, banana ketchup, a takeoff on *jufran* and *mafran*, traditional Philippine hot and spicy banana-based condiments, is produced. Tomato ketchup was also used to make other condiments. For instance, many recipes for barbecue sauce contain ketchup. While barbecue has a long history, the first actual use of the term barbecue sauce does not appear until the mid-twentieth century.

### Mayonnaise and Other Condiments

Mayonnaise was based on *aioli*, a Spanish sauce that combined olive oil and egg that probably dated back to Roman times. In the seventeenth century, the French took this basic notion, refined it, and gave the world a unique sauce that they called *mayonnaise*. It could stand alone or could be employed to make other sauces. Mayonnaise, one of the French “mother sauces,” was exported to England and to America, where it was used as a sandwich spread in the nineteenth century. Around the turn of the century, it was first manufactured as a commercial product in America.

Mayonnaise was initially used on salads or to make salad dressings and other condiments. For instance, commercial tartar sauce is composed of mayonnaise, relish, and spices. Salad dressings have been consumed since ancient Roman times. Commercial dressings today include ranch, italian, blue cheese, thousand island, french, and caesar.

The rapid success of many condiments can be attributed directly to the globalization of American fast food establishments. For instance, ketchup, mustard, pickles, pickle relish, and mayonnaise are spread on hot dogs, hamburgers, and french fries.

**CONSUMER PROTESTS.** When enough consumers become dissatisfied with their conditions, such as the lack of nutritional food, the cost of food, and the way food is produced, they have a tendency to organize with other like-minded people. They are then likely to take part in some forms of social action. Compared to a spontaneous riot, protests tend to be relatively organized and are often catalyzed by special-interest groups—sometimes referred to as the “protest industry.” That term is appropriate since some such groups are very well established and influential. They use a variety of techniques to draw attention to their cause and to obtain support.

Food riots and food protests are ongoing phenomena. Historically, food riots, common in the eighteenth and early nineteenth centuries, have generally occurred when food is in short supply, whether this is due to weather, insect infestation, or weak economic conditions and increased food prices. For example, as a result of poor harvests in late eighteenth-century France, the price of bread soared, and riots were common in all areas of the country. French farmers have become famous for protesting government policies by driving tractors to Paris. The Great Irish Potato Famine of the mid-nineteenth century was the launching point for bloody riots. It eventually led to the great Irish emigration and to technological advances in agriculture. The food riots of this period led to more organized food protests as basic needs for nutrition gave way to demands for food safety and security.

Increased food prices, along with insufficient and unequal distribution of food rations during both World Wars led women to protest all over Europe. More recently, economic mismanagement and rising food prices in Argentina led to riots despite the abundance of food on supermarket shelves. Likewise, riots in some African countries are commonplace as disreputable governments

Protesters dressed as cows protest outside the Ministry of Agriculture in England over the handling of Mad Cow Disease. COURTESY OF AP/WIDE WORLD PHOTOS.

hoard food shipments from other nations for themselves while starvation is rampant in the poorer, more rural parts of the country.

Protests also occur when food is plentiful, but these protests and boycotts can be more political in nature. For instance, the 1965 grape boycott in California began as a result of wage disputes between domestic union workers, migrant workers, and grape growers. When negotiations between growers and workers stalled, union leader César Chavez called for a national boycott of table grapes. The four-year dispute led to more equitable contracts for workers and was the most successful boycott in American history.

Fears over food quality and safety are also catalysts for protest. In the 1980s, a national protest group used a public relations agency to launch a protest against the chemical Alar, which was used to keep apples on the tree longer and produce redder colors. However, the U.S. government did little to limit use of the chemical, and sales of the product continued, as did the spraying of apples, under consumer protest that children's lives were at stake. By 1989, apple sales had fallen by half, and the manufacturer was forced to take Alar off the market. The event led to some lawsuits by apple farmers against the network that broke the story that led to the consumer boycott.

More contemporary food issues attracting global attention include food safety, such as "mad cow disease" in Europe and the possible spread of this disease to humans. Mad cow disease, or bovine spongiform encephalopathy (BSE), is a neurodegenerative disease that eventually destroys a cow's brain. It has been responsible for the slaughter of millions of cattle and other food animals. Its human form (Creutzfeldt-Jakob Disease) has killed 111 people in the United Kingdom alone (*New Scientist*, 20 July 2002). The death toll could rise because the incu-

bation period is long (the "second wave") and because the disease could spread to other animals or countries. Protests over BSE have arisen on several fronts. Farmers protest that they are not being compensated for their losses by insurance companies or the government. Consumers protest both the marketing of the suspected meat and the slaughter of affected animals.

Another issue that is prompting protests involves the genetic modification of food. That is, genes have been inserted or removed to provide specific benefits. Foods have been genetically modified to resist disease, adverse weather conditions, and insects, and are modified to contain beneficial human nutrients. Proponents of biotechnology report that the seeds are environmentally safe, reduce the need for pesticides, and can be modified to include useful nutrients. Opponents are concerned that genetically modified foods may have hidden health hazards, may be detrimental to the development of the poorest countries, and may be environmentally unsafe.

Protests against genetically modified food have occurred more often in Europe than in the United States. This reflects different cultural views on science, technology, and agriculture. There are also differences in the government's credibility. Europe is regulating the process of genetic modification based on a variety of political and economic interests.

One of the main things to note about consumer protests is that they are often well-funded and centrally coordinated by groups who have a vested interest in the outcome of the protests. Most average consumers have little interest in or even awareness of some of the protests. For example, a coalition including various players in the organic industry and some environmental groups has worked together to raise public fears about the safety of modern food production technologies (including pesticides and genetic modification). The ultimate goal is to increase the sales of the more profitable organic foods. Through their campaigns they have been quite successful.

Overall, it is interesting to note how the focus of food protests shifts as a country goes through the economic development process. In poor countries, the main concern involves getting enough food to eat. It is only in the richer countries that consumers are able to spend time and money to make sure that their foods are of high quality and safety. What is certain is that the future will see more protests over both sets of issues.

**CONSUMPTION OF FOOD.** Did humans once have some instinctive knowledge about which foods to eat for good health? No one knows, but whatever inherent wisdom about nutrition humans might once have had has been wiped out in most parts of the world by a persistent background "noise": from infancy, people are bombarded by the selective, but constant, advertising of certain foods and drinks. Advancing globalization has sent products such as cola drinks to remote parts of the world, and advertisements for them have been so pervasive that some people believe that water cannot satisfy their thirst. Social aspects of eating have also changed in some countries, from regularly scheduled family meals to a pattern of random snacking. Is this the way humans were programmed to eat, or is it the result of marketing? Scientific aspects of nutrition also influence food consumption in many countries as consumers decide whether to eat nutritional foods or those that have no nutritional value.

### Why Humans Eat What They Eat

What, when, how, and why people eat and drink is linked not only with biological needs and the availability of various foods, but also with the customs, aspirations, and expectations of their societies. The quantity and quality of food consumed, whether people "graze" or eat discrete meals, the emphasis given to different foods (or to desirable body shapes related to diet), and the customs surrounding eating have varied throughout history and within cultures. Nevertheless, the major influence on the daily diet has been the availability of food. Humans can survive only a few days without water and, while the average healthy person can stay alive for weeks or even months without food, this will have adverse effects and sometimes cause permanent health problems.

As well as being a biological necessity, eating and drinking are enjoyable activities, and the more varied the foods available, the more most people will eat. Nutritionists generally recommend eating a large variety of foods as this increases the chances of achieving nutritional adequacy and lowers the risk of a high toxin load. Against this, however, the problem of overconsumption now affects the wealthiest countries in the world, coexisting with malnutrition in many areas. Cultural factors—taboos about eating certain items, appropriate times for meals and snacks, and the way food is distributed among members of a social group—have also played a role historically.

When debate involves morality, scientific considerations may be beside the point. Some people think that food choices have a moral dimension, for example, regarding it as wrong to kill animals for food. Scientists, however, who study the ideal proportion of fatty acids in

cell membranes maintain that, once our ancestors diverged from the apes, they adopted a diet that consisted primarily of marine creatures and plant-based foods. In *The Heretic's Feast: A History of Vegetarianism*, Colin Spencer, himself a vegetarian, traces the history of our ancestors' diets to show that human survival depended on being omnivorous, and notes that our close relatives, the chimpanzees, ate meat, although not in great quantities. Gastroenterologists support this, arguing that the human intestine is designed to digest both animal and plant foods. About 500,000 years ago, the discovery of fire almost certainly encouraged meat consumption because the heat softened connective tissue and produced enticing aromas and flavors. Having the physiological ability to eat any kind of food, however, does not mean that humans must be omnivores. Many people adopt a vegetarian lifestyle because of their religious or philosophical convictions without sacrificing a nutritionally balanced diet.

Until the twentieth century, the environmental consequences of the foods people consumed were largely ignored. With an increasing world population, however, the sustainability of the world's food supply has forced itself onto the agenda. Equity issues also arose because some countries were using up scarce energy and water resources to produce an ever-expanding range of foods for an overfed population while others starved because they did not have access to basic resources. The United States, for example, had approximately 5 percent of the world's population but consumed 26 percent of the world's energy resources as the twenty-first century began.

Growing grains or legumes to feed animals, rather than letting animals graze on lands not used for human crops, is particularly wasteful as lot-feeding requires approximately 100 times more water to provide about 1 kg of animal protein than is needed to produce the same amount of plant protein (Pimmental, Houser, and Preiss, 1997). There are also nutritional implications. Researchers found that the meat from grain-fed animals had fewer essential fatty acids than meat from grass-grazing animals, and there are also concerns about the effects on humans of the use of growth hormones to increase the size of cattle or their milk yield.

### Myths, Customs, and Manners

Myths and superstitions associated with food exist in all cultures. Few people believe that cucumbers must be scored "to let the poisons out," tomatoes are no longer believed to be "toxic," and the belief that eating the brains of heroes will lead to bravery has almost disappeared, but myths abound, even when science has proven them wrong. As the twenty-first century began, for example, many people still believed that eating meat, especially beef, causes aggression. Others maintained that the body is unable to digest protein and carbohydrate at the same meal, which would make it impossible to digest foods containing both, such as human milk, nuts, seeds, grains,

and legumes. Forty percent of the population in the United States is taking vitamin and herbal supplements because they believe advertising claims that vegetables and fruits no longer contains vitamins.

Some enduring customs relate to religious beliefs about food. These include feasts and fasts, kosher foods, foods regarded as “unclean,” forbidden foods, “holy” foods, or the supernatural doctrine of the Roman Catholic and Eastern Orthodox Churches asserting the eucharistic transubstantiation of bread and wine into the body of Christ.

Wealth or social status also determines which foods people can afford to eat, although this can change over time. When peasants ate coarse whole-grain breads, for example, white bread was preferred by the upper classes. Because scientists determined that whole-grain breads are more nutritious than breads made of bleached white flour, highly educated people began to eat the more expensive whole-grain breads.

Etiquette also varies around the world. Where food is consumed with the hands and toilet paper is not used, it is customary for only one hand to be used for eating. Touching food or shaking hands with the hand used to wipe oneself in such countries is regarded as bad manners because it is unhygienic. Many people once considered it bad manners to eat while walking along the street, although the ubiquitous habit of snacking has led to greater tolerance of this practice.

In the West, many books have been written on table manners, but context is everything when it comes to etiquette. Much depends on the culture and social class, the context of the meal (a formal dinner demands adherence to complex social rules whereas a casual snack requires few or none), and the social group involved. In some cultures resting one’s elbows on the table or making loud slurping noises is considered bad manners, whereas other societies have no objection to such habits. The polite way to put down cutlery at the end of a meal varies around the world, and sometimes even within a country. Some cultures regard burping at the end of a meal as a sign of satisfaction, even as a compliment to the cook; others think it is rude. Passing gas also has varying acceptance. In Western societies, some believe passing wind (flatulence), even in private, indicates some medical problem. In fact, the quantity of gas produced is related to what has been eaten. As helpful bacteria break down dietary fiber and some types of starch, they produce beneficial acids with gas as a by-product.

### **Convenience**

Over the past one hundred years or so, anything that reduced the need for domestic labor was popular, including kitchen appliances and convenience foods. Scholars such as Lebergott (1993) estimated that the average American housewife spent thirty-two fewer hours a week on meals and housecleaning in 1975 than she did in 1910. The noted nutritionist and ecologist Joan Gussow found that much of the time people once spent in the kitchen

is spent watching television, and watching television is how they learn about the latest convenience foods, which saves them more time, which allows them to spend more time watching television so they can be persuaded to buy more convenience foods, and so it goes.

By the end of the twentieth century, marketing of fast foods had shown how easy it is to change eating habits. Starting from scratch almost fifty years earlier, by 1997 McDonalds had 23,132 outlets in more than one hundred countries, with annual sales of \$34 billion. The standardized foods offered by fast-food chains had come to appeal to all socioeconomic groups and changed food culture for many people in the West, encouraging eating-on-the-run rather than sit-down family meals. Somewhat ironically, the only time some families eat together is at a fast-food restaurant. Research done in the 1990s (Stanton) found that children liked fast-food restaurants because they felt welcome, the family was relaxed and happy (because no one had to cook), and there were playgrounds and gifts. The food was relatively unimportant, but they liked the standard menu and the fact that there were no vegetables except for French fries. One McNair survey in Australia (1999) found that the “golden arches” had become, in just twenty years, more recognizable as a symbol than the crucifix. As one commentator put it, “Hamburgers are now outselling heaven.”

When fast-food hamburgers appeared in Rome in 1989, Carlo Petrini was so horrified that he began the Slow Food Movement, intended to counter what he considered the degrading effects of industrialized food and fast foods. In 2002, the movement operated *Convivia* in forty-five countries and was spreading but had not yet reached sufficient critical mass to alter the average consumer’s eating habits.

### **Nutritional Science**

Nutritionally, fast foods are a disaster: they have high levels of added saturated fat, salt, and sugar. An average fast-food hamburger contains twice as much fat as one that was served by individual outlets in the 1970s. Few fast foods feature vegetables, apart from fat-soaked potatoes, and the replacement of regular meals with fast foods partly accounts for the fact that most people in Western countries eat fewer vegetables than nutritionists recommend for good health.

Despite the increase in convenience foods, however, nutrition was gradually becoming more important in influencing consumers’ decisions about which foods to buy. This is nothing new. Hippocrates said 2,400 years ago, “Let food be thy medicine.” But it was not until the twentieth century that vitamins, amino acids, fats, and fiber were isolated and identified, and researchers have since been trying to unravel the role of hundreds of protective phytochemicals in plant foods.

Nutritional science can encourage change if it gets enough airtime to compete with the time purchased for “informing” consumers about the latest unhealthy con-

venience foods. Olive oil, for example, was vital to Mediterranean cuisines for thousands of years, but was shunned as food in other countries, although it was used as a skin moisturizer. Once studies showed its healthfulness, olive oil became popular in cooking beyond its original homelands and was outselling all other oils in Australian supermarkets by the close of the 1990s.

Nutrition may not, however, always overcome social custom. For example, among preschool children in Australia, boys are given more meat than girls, although there is no difference in their need for meat's nutrients. The assumption that men should receive more meat than women ("feeding the man meat") then continues into adulthood, with Australian men consuming more than one and a half times as much meat as women, even though women have greater requirements for meat's most important nutrient—iron.

There are also fashions in dietary recommendations and changes as new data becomes available. Consumer confusion is also fed by self-styled "experts" whose book sales depend on new diets that have little or no scientific support. Basic governmental advice to consume more vegetables, fruits, and whole-grain cereal products and less saturated fat, sugar, and salt has not changed, but governments are not immune to influence from powerful lobby groups that want more positive spin for their products.

### Meals and Snacks

Studies with adults have shown that eating "small and often" can produce benefits for metabolism, reduce blood fats, and lower blood glucose levels. Babies who feed spontaneously on their mother's milk have fewer problems with health and weight than those who are given regulated formula feeds of known quantity.

Does this research mean that snacks are preferable to meals, and would a grazing pattern of eating fit our genetic background better than restricting food to three major meals a day? While nothing is true for everyone all of the time, in countries where snacking is common, so is obesity; where snacking is less common, as in France, obesity rates are lower. The grazing pattern suits makers of processed snack foods (who fund some of the positive snacking studies), but most studies favoring snacks have provided the snacks calculated to fit each individual's daily requirements. In practice, self-selected snack foods are less nutritious, and, for those who overeat every time they eat, snacking may not be ideal.

### From the Past to the Future

Three prominent milestones in the changing human diet can be identified:

- hunter-gatherer diets consisting mainly of meat, birds, insects, and fresh or saltwater creatures plus fruits, seeds (including wild grasses), nuts, various green vegetables, yams, and other edible plant materials;

- the agricultural, farm-based period that began about 10,000 years ago when animals were domesticated to produce meat and milk, and crops of grains, fruits, vegetables, and nuts were planted, first for individual families and then also for urban dwellers;
- the technological age, which extended basic farm-produced foods using processing and additives to increase shelf life and provided a broader range of foods padded with extra sugars, fat, salt, flavorings, and colorings. This period decreased the role of home cooking in favor of mass-produced, ready-to-eat foods. At the beginning of the twenty-first century, 46 percent of the food dollar in the United States was spent on foods prepared outside the home.

Genetically modified (GM) foods began to extend the role of technology at the end of the twentieth century. Initially, such foods benefited only those who owned seed stocks, but this technology can also produce foods capable of filling particular nutritional or social needs. GM technology created unrest in Europe and many other parts of the world, especially because of concerns about the integrity of local foods and the plight of poorer nations forced to exchange subsistence family farming for GM crops whose seeds are owned by large agribusiness companies.

Each of the major dietary changes throughout human history has had social and environmental implications. Hunters (usually men) were given greater status in many communities than gatherers (usually women and children). Farming also divided society into owners and workers. That distinction was transformed in developed countries by mechanization and takeovers of small family farms by large commercial companies. Rural communities were impoverished and turned into ghost towns as people left, agribusiness took over what had been family farms, and farming the resulting large farms was done by machine. Whatever tasks remained that required manual labor were left to migrant workers.

The technological age of highly processed foods encouraged people of all ages and socioeconomic groups to purchase foods prepared outside the family kitchen. Increased use of such foods caused cooking skills to degenerate and even changed the physical layout of some dwellings, where there is no longer a dedicated kitchen.

The environmental effects of dietary changes were not taken into account until the end of the twentieth century. Hunting, for example, contributed to some animal species being wiped out. Farming based on technology and driven by the bottom line, with its inhumane methods of raising animals, lot-feeding, and monocultural crops, required increased use of fertilizers, herbicides, and pesticides, which caused environmental problems such as increased salinity, poor soil fertility, poisoned or polluted groundwater, loss of many plant cultivars, and climate change due to massive land clearing. As the

twenty-first century began, the conflict regarding the full environmental costs of GM crops was just getting started.

**COOKBOOKS.** Though essentially manuals of instruction for the preparation of food, cookbooks are now coming into their own as a genre. They are rich sources of information not only about the foods of a given period but about the people who cooked and consumed those foods. Scholars are turning to cookbooks for evidence of cultural values, and are showing a new appreciation for knowledgeable writers who write well about food and its context. Cookbooks have been moving away from their origins as humble recipe books to glamorous books with lavish photographs, more likely to be found on living-room coffee tables than kitchen counters. As a result of these enhancements, cookbook collectors are not only cooks and food scholars, but people who enjoy reading recipes with beautiful photographs of dishes they may never cook.

The history of cookbooks within a culture reflects its food traditions, so that while France has produced a

rich cookbook literature, other countries have not. The evolution of restaurants in France, especially since the early nineteenth century, generated books written by chefs who have codified their recipes. But in a country such as Ireland, which has no restaurant tradition, historic recipes are to be found in the handed-down oral tradition of home cooks.

In America, early settlers brought with them books written in England, and later plagiarized recipes from British books for an American audience. Not until 1796 did an authentic American cookbook appear when Amelia Simmons published *American Cookery*, a collection of recipes that included such New World ingredients as corn meal and cranberries. Other decidedly American landmark cookbooks were published by Mary Randolph, Eliza Leslie, and Lydia Maria Child, whose *Frugal Housewife*, published in 1829, was later published in England and retitled *American Frugal Housewife*.

#### Nineteenth-Century Cookbooks

Because the mission of a cookbook is to instruct, the voice present in the text is authoritative and often didactic. In nineteenth-century America, the division of labor within most families required women to be responsible for the smooth running of the home and the proper feeding of husbands and children. Apart from offering recipes, cookbook writers of the period who saw themselves as guardians of the public morality took on the added responsibility of advising housewives on how to manage their duties.

Catherine Beecher, who carved out a career for herself by promoting the concept that housewives were professionals, believed that American women had control over the well-being of the country's democratic system and its future as a Christian nation. Beecher dedicates *The New Housekeeper's Manual* (1873) "to the women of America, in whose hands rest the real destinies of the republic, as moulded by the early training and preserved amid the maturer influences of home." To her mind, cooking well was the patriotic duty of homemakers. Beecher, who came from a family of preachers, was given to florid pronouncements such as these comments on the results of bad cooking: "Green biscuits with acrid spots of alkali; sour yeastbread; meat slowly simmered in fat till it seemed like grease itself, and slowly congealing in cold grease; and above all, that unpardonable enormity, strong butter!" She introduces her recipes declaring, "How one longs to show people what might have been done with the raw material out of which all these monstrosities were concocted!"

Another influential nineteenth-century voice was that of author Marion Harland, pen name of Mary Virginia Hawes Terhune, a woman whose privileged circumstances never prevented her from commanding the practical details of housekeeping. She published successful novels and advice manuals that gained her the confi-

dence of readers. Her extraordinarily popular *Common Sense in the Household* (1871) holds that “it is a mistake of Christian civilization to educate girls into a love of science and literature, and then condemn them to the routine of a domestic drudge.” Her task, as she saw it, was to encourage and reassure her readers by calling a kitchen disaster “a stepping-stone to success,” for, as she puts it, “not to do it right is the next thing to success.” Her book is a thick collection of typical American dishes that probably would have been cooked and served to Harland by the servants she employed in her affluent home. On the other hand, the assured Catherine Beecher, who had developed a system of scientific housekeeping, never had a home, husband, or children.

While the writings of Marion Harland and Catherine Beecher may project images that were different from the real women, there is consistency in their belief that a moral society depended on the skills of women working within the domestic sphere. Another writer of this period, Hetty Morrison, was, however, an out-and-out opponent of this view as her book, *My Summer in the Kitchen* (1878), makes abundantly clear. Morrison rails against the social forces that put women into the kitchen as though it were their natural habitat, and like Harland, deplores the quandary facing girls who were given no training in the domestic arts, yet were expected to be highly skilled homemakers when they married. But, unlike Harland, Morrison confronts the injustice of it all:

The cunning of the serpent was nothing to that of man when he founded the institution of the kitchen and then placed woman there to tend it for him. Woman left to her natural instinct, would satisfy her appetite with a few chocolate caramels and an occasional cup of tea. But when her ‘lord and master’ appears upon the scene, then and there is hurrying to and fro, and fires and faces blaze, and terror, and death, and destruction go forth among the feathered, and furred, and fanny tribes.

### Wartime Cookbooks

The authoritative voices in cookbooks can support the status quo by reinforcing current social values or they can dissent from conventional thinking. Another important function of cookbooks has been to help families in times of war when customary foods are scarce and often rationed. But even in times of national crisis, cookbook authors have varied in their approaches to how this challenge should be met.

During World War II, home economists and dietitians threw themselves into the war effort by educating the public about nutrition, and by trying to persuade all citizens to eat their fair share of what was allotted. Often wives would turn over their portion of the ration to husbands and sons, a sacrifice food writers hoped to correct. For instance, it was suggested that, instead of boiling eggs, they could be stretched further by scrambling them with breadcrumbs.

Cookbooks often serve as vehicles for ethnic identity. While *La cocina vasca* (The Basque Kitchen) is written in Spanish, the recipes also feature their names in the Basque language. Perhaps most important is the cover image, which emphasizes the point that the Basque kitchen is also the dining room. Shown here is the Barcelona edition of 1936. ROUGHWOOD COLLECTION.

**British wartime cookbooks.** This theme of making-do was found in British cookbooks (cookery books) with titles such as *Cookery under Rations* (1941), *Health for All Ration-Time Recipe Book* (1948), and *Feeding the Family in War-Time* (1942). Their authors tended to be domestic scientists or dietitians whose task was to suggest cooking tips to keep families eating as well as possible within the limitations imposed by wartime rations. Their books make clear that monotony of diet was a big challenge. While such old-shoe crops as cabbages, Brussels sprouts, and oats grew comfortably in the British climate, such favorites as peaches, tomatoes, and wheat had to be imported and were therefore scarce. Most British wartime cookbooks are fairly somber in their instructions for plain and healthy recipes, often substituting ingredients at hand for more desirable ones.

One writer, Margaret Brady, saw fit to use the crisis of war as an opportunity to promote her prewar commitment to vegetarianism, seeing virtue in brown rather than white bread, less meat and more vegetables, and sugar-free desserts. *Health for All Ration-Time Recipe Book* (1948) has directions for such concoctions as nut and

carrot rissoles, nut meat stew, and oatmeal soup, and puts emphasis on the healthful properties of raw foods, a reminder that cooking fuel also had to be conserved.

Wartime exigencies turned cookbook writers into virtuous citizens. For example, Doris Grant, who was not a food or health expert before the war, was motivated to learn more about these subjects. *Feeding the Family in War-Time* (1942) has advice on healthy living followed by recipes for such fare as wartime ice cream (made with soy flour), potato sausages (made with oatmeal), and salads made with grated carrots, a vegetable that grows abundantly in the British Isles.

Marguerite Patten sums up wartime conditions in England in *We'll Eat Again: A Collection of Recipes from the War Years* (1985), a backward glance at how the country managed on the available food supply. She offers the surprising information that there was an improvement in overall health as measured by a decline in infant mortality and an increase in the average age of death from natural causes. The recipes and advice collected in this book make clear that poor people who subsisted mainly on bread and other starches were urged to eat more meat, eggs, and fresh produce than ever before, resulting in improved health statistics. The diet of the upper classes was also improved because people were obliged to ease up on the traditional prewar English breakfast of fatty meats and eggs, and the customary rich cakes and pastries served at afternoon tea.

Not all wartime cookbook writers addressed the needs of the body alone. In her *Come into the Garden Cookbook* (1942), Constance Spry explains, "I write this book for the people who see nothing unseemly in being enthusiastic about food, and who are willing to turn attention and energy into procuring and preparing it." Not for her are sausages extended with breadcrumbs or cabbage stuffed with oatmeal. She aims to grow good food in her garden, cook it skillfully, and pass on to others directions and encouragement for doing the same. All too aware that British cooks did not prepare vegetables with the respect they deserved, she offers excellent recipes to get people through wartime eating not just well, but deliciously so. As for gardening, she sees such activity as "a cure for frayed nerves and restless minds [that] can ease unhappiness and lighten apprehension." Spry's wartime cookbook is written as much for the spirit as for the body. Unlike other books of the time, hers does not reduce food to its nutritional components but instead describes it as a way to bring comfort and joy as well as sustenance to a population under stress.

**American wartime cookbooks.** In America, abundant advice about wartime cooking routinely appeared in articles and books, most of them offering practical information about gardening and canning as well as thrifty tips for dishes not requiring too much of what was rationed. A recurring theme in this material is that American housewives were performing their patriotic duty by following the advice offered by this assemblage of experts.

Alice Bradley, the principal of Miss Farmer's School of Cookery in Boston and an influential food writer of the time, published books that explained how to plan meals, shop for ingredients, and cook well despite shortages. Her dedication in *The Wartime Cook Book* (1943) is to "Women who are cooperating in winning the war by using those foods of which we have an abundance in such combinations as to make themselves and their families strong." The moral message was not dissimilar to what nineteenth-century women had been told by cookbook writers who believed that the health of the nation relied upon the smooth running of the home and the proper cooking of family meals. Bradley's wartime tips include substituting soybean flour for wheat in thickening sauces and soups, using a pressure cooker to conserve heat and retain vitamins in vegetables, replacing sugar with honey or syrup in fruit desserts, and making use of such animal parts as the liver, heart, kidney, sweetbreads, tripe, and tongue. She has a recipe for "heart ragout" that calls for "leftover heart" as its first ingredient, causing one to wonder what else Miss Bradley kept in her refrigerator. Always in the role of a teacher who dispatched cooking information with clarity and economy, Miss Bradley was never given to moments of speculation about living through difficult times.

Such thoughts were more in the mind of M. F. K. Fisher, who in 1942 brought out *How to Cook a Wolf*, a book about eating well during wartime. She states: "I believe that one of the most dignified ways we are capable of, to assert and then reassert our dignity in the face of poverty and war's fears and pains, is to nourish ourselves with all possible skill, delicacy, and ever-increasing enjoyment." Fisher was speaking to the human heart and not just to its stomach, and in so doing was taking on the food-writing establishment, who never looked beyond the mundane issue of the well-balanced meal, a concept Fisher loathed. Convinced that human requirements vary, Fisher reserved the right to eat just toast for breakfast if she felt like it, while others might feel better dining on protein alone. This is not to say that Fisher is never practical, for she does provide seventy-three wartime recipes for favorite foods using cheap and available ingredients, and it is a measure of her acclaim as a food writer that those recipes continue to have wide appeal. She talks about the comfort of such simple dishes as polenta, spaghetti, and kasha. But she is careful to say that the polenta must be made with coarsely ground cornmeal from Italian grocery stores, the spaghetti must not be overcooked, and the kasha can be made heavenly by the addition of butter and sauteed mushrooms. *How to Cook a Wolf*, a book about food that should have lost its audience when the war was over, is still read with curiosity and pleasure. For M. F. K. Fisher, writing about food was a way to share experiences and feelings, with her most memorable writing coming out of the exigencies of war. At a time when most other food writers were watering down butter or extending meat loaves and

Cookbooks by famous restaurant chefs have been an important genre since the eighteenth century. Chef Karl Sroubek's *Wie kocht man bei Sroubek* [The way we cook at Sroubek's], published in 1911, showcases dishes from this once famous temple of Central European cookery in Prague. ROUGHWOOD COLLECTION.

hashes with still more breadcrumbs, Fisher was advising her readers that "since we must eat to live we might as well do it with both grace and gusto." It was an inspiring message for a frightened world.

### Modern Trends

Cookbooks have continued to reflect changes in American life in every decade following World War II. Some cookbooks of the 1950s reflect the prevalence of short-cut cooking and the use of technology. In *The Can-Opener Cookbook* (1951), Poppy Cannon tells us that "The use of a can opener may not be news, but the gourmet approach definitely is." The home freezer, an appliance that was increasingly popular after the war, inspired such books as Anne Seranne's *Your Home Freezer* (1953), which taught how "gourmet" dishes could be prepared in batches and frozen for a rainy day. Postwar inflation also prompted books that emphasized thrift. For example, Ida Bailey Allen's *Solving the High Cost of Eating* (1952) and James Beard's *How to Eat Better for Less Money* (1954) taught

Americans how to best manage their food budgets. By 1961, Lila Perl had published *What Cooks in Suburbia*, with a table of contents that refers to "Pot-luck from the deep freeze" and special recipes for dinner parties that were in vogue during this period. In the same year, Julia Child published *Mastering the Art of French Cooking*, the book that inspired many adventurous American cooks to take on the challenges of French cuisine.

By the late 1960s and the 1970s, the country was seeing a radicalized youth culture developing in response to antiwar protests and the movements for civil rights and women's rights. A group called the Friends of the United Farmworkers produced a cookbook in 1976 to raise money in support of grape pickers seeking fair wages. This book is a reminder of the successful grape boycott that was observed by many American families. A short time later, the Bloodroot Collective, a feminist commune that runs a Connecticut restaurant, produced *The Political Palate, a Feminist Vegetarian Cookbook* (1980). Their political convictions included the use

of vegetarian, organically grown foods and excluded the celebration of traditional holidays that were seen as endorsing “a theology and value system which continues opposition to abortion and the Equal Rights Amendment [and] believes homosexuality to be a sin or disease.” The collective’s political approach to food is inclusive in that their recipes take in Native-American sources as well as a range of other ethnic influences.

American cookbook publishing has become noticeably ambitious in that it covers international cuisines of all kinds. Cookbooks are often lavishly illustrated, many of them authored by well-known chefs. Another trend has been in books with a nutritional slant, most frequently on weight loss, a clear indication that the American book-buying public is not suffering from deprivation or the need to economize. An affluent, increasingly overweight society has become a ready audience for a continuing supply of books that promise painless solutions to the vexing problem of weight control.

Cookbooks have value as historical documents that can provide us with insights into people or groups by examining their relationship to food. Any culture that has a tradition of cookbook writing can be similarly approached. Until recently, researchers have overlooked or trivialized cookbooks. Now these books are beginning to be recognized as valuable records of our past, full of information waiting to be interpreted.

**COOKBOOKS, COMMUNITY.** Community cookbooks (also known as compiled, regional, charitable, and fund-raising cookbooks) are a unique genre of culinary literature. These volumes are produced collaboratively by volunteer women from charitable organizations, churches, synagogues, heritage associations, clubs, schools, and museums, among others. They represent the group’s members and cuisine. The practice of producing these volumes to raise money began shortly after the end of the Civil War (1860–1865) when they were compiled by Northern Protestant churchwomen to raise money for the Union Army wounded and their families.

#### Research Tool for Culinary Historians

Community cookbooks are a rich source for the culinary historian and foodways researcher. They can be read like texts, accurate and reasonably complete reflections of the food habits of the communities that produce them. Unfortunately, community cookbooks have only recently been taken seriously, and the greatest challenge for the researcher may be in locating the books (see the bibliography below). In defining “community,” these books include certain people and traditions, and exclude others. For example, a cookbook prepared by a religious group that shuns alcohol will not include a drinks section or use liquor in its recipes. These volumes provide records of regional culinary cultures, and the historical, philosophical, and religious background of their compilers.

Community cookbooks focus on home cooking, often documenting regional, ethnic, family, and societal traditions, as well as local history. Some of the earlier ones served to preserve the cooking of the homeland, those countries in Europe and Russia that produced the great wave of immigration between the 1880s and the outbreak of World War I. The cookbooks often distinguish between common, everyday foods and special occasion foods; for example, two Midwestern cookbooks, *What Albion Congregationalists Eat* and *Our Favorite Recipes* mention that meat loaf or baked beans are served only to family, whereas festive dishes were reserved for holidays. Although not submitted to the rigors of professional recipe testing, the formulas have the weight of years of experience in the home kitchen. Indeed, many of the cookbooks advertise their recipes as “tried and true,” providing access to the collective culinary skills and expertise of many women.

The volumes provide insight into food preferences as well as those dishes that are disliked or taboo and simply not included. For instance, the *Swedish American Cook Book*, published in 1941 by the West Hartford [Con-

necticut] Ladies Aid Society, includes a wealth of recipes using canned crushed pineapple, such as Pineapple Meringue Pie, Pudding, Frosting, Icebox Dessert, Pineapple Loaf, and Skillet Sponge. This book, as well as others that focus on a particular ethnicity, offers clues to the degree of assimilation of the community. Clearly, the extensive use of canned pineapple reflects the embracing of American processed foods rather than Swedish heritage and tradition. Similarly, *The Johnstown Area Heritage Association Cookbook*, published in Johnstown, Pennsylvania, in 1989, includes Mexican recipes based on the migration of laborers into the area looking for work in the mines and mills. It documents the celebration of the Feast of Our Lady of Guadalupe, the patron saint of Mexico, every December by this community, a tradition that was abandoned toward the end of the twentieth century.

### A Few Best-Sellers

Community cookbooks have proved an extremely effective means of quickly raising funds. Some, in fact, have earned millions of dollars, and transcend popularity in their original communities to take on a life of their own. One of the best known, although it was actually prepared by only two women, is *The Settlement Cook Book*, subtitled *The Way to a Man's Heart*, first published by the Milwaukee Jewish Mission and The Settlement in 1901 to benefit newly arrived Jewish immigrants. It has gone through more than forty editions, and a hundred years after its first publication it had sold over 1,500,000 copies. It was one of the first ethnic cookbooks published in English, and one of the earliest to include German-Jewish recipes. Another big seller has been *Forum Feasts: Favorite Recipes of the Forum School*, first published in 1968 to raise funds for a school for emotionally disturbed children in northern New Jersey. The fact that *Forum Feasts* went through twenty printings and sold more than 300,000 copies before it went out of print shows that it was bought by great numbers of people who had no interest or involvement in the Forum School. Part of the widespread appeal of community cookbooks may well be the strong stand they make for home cooking.

Today, some community cookbooks are expensively and professionally produced. *The High Museum of Art Recipe Collection*, published by an art museum in Atlanta, Georgia, in 1981, contains four-color plates of museum paintings and features chapter headings such as "Dinner at Eight: Recipes for Seated Dinners at Home," which reveal a cosmopolitan community where gracious living and entertaining is the norm. Another chapter is entitled "Before the Game and After the Show: Prized Recipes for Brunches and Late-Night Suppers"; the "Picnic" chapter includes "elegant picnics."

### Community Cookbooks as Women's History and Literature

Community cookbooks are uniquely women's literature, created by and for women, one of the earliest ways in

which women could relate their stories and history. Like quilts and needlework that have also been perceived as trivial, domestic crafts, community cookbooks have often provided the prime, perhaps only, vehicle for women to express themselves. Since they fall under the rubric of "good works," the cookbooks evolved as permissible and appropriate activities for women for whom professional careers might not be acceptable in their own eyes or those of their communities. Some of the books go well beyond these goals to provide a platform for a political or social agenda. *Our Sisters' Recipes* (Pittsburgh, 1909), a Jewish community cookbook, uses a frontispiece of an African-American woman with a head scarf, apron and spoon to symbolize that the sponsors had achieved American middle-class status and could afford to employ cooks. the National Council of Negro Women's *The Black Family Dinner Quilt Cookbook* (1993) pays tribute to a civil rights leader and discusses food traditions.

By soliciting and contributing recipes for the cookbooks, women participate in a women's network, similar to quilting. As Anne Bower points out in *Recipes for Reading*, these are women "bound together by recipes" (p. 14). Community cookbooks institutionalize the informal practice of recipe exchange among women. This dynamic process has involved and defined a vast community of middle-class women, telling stories that are both personal/autobiographical and relational. By writing their cultures into the cookbooks, these women establish their identities and reveal their history, a major aspect of female cultural heritage.

**COOKIES.** See **Baking; Biscuit; Pastry.**

**COOKING.** Cooking often means the transformation of raw food by the use of heat. Conceived this way, cooking's contribution to human pleasure, culture, and survival could hardly be overstated. When interpreted more widely to include everything involved in the preparation of meals, cooking is even more extraordinarily time-consuming and far-reaching.

Cooking is so universal that it has even been proposed as the distinguishing trait of *Homo sapiens*. In a journal entry for 15 August 1773, social observer James Boswell noted that other species possessed the abilities of toolmaking and rationality, but "no beast is a cook," and his definition of humans as the "cooking animal" was the subject of much discussion and amusement at dinner tables. The paradigmatic cultural transformation of "raw" into "cooked" was brought into a more recent scholarly context by the anthropologist Claude Lévi-Strauss, who wrote in *The Raw and the Cooked*, "Not only does cooking mark the transition from nature to culture, but through it and by means of it, the human state can be defined with all its attributes" (p. 164).

Modern recipe books demonstrate cooking's great array of visual, olfactory, and gustatory effects. Increasing the attractiveness of food and altering its nutritional properties, cooking has served fundamental social and cultural purposes. Cooking made possible the agrarian mode of production, based on food storage. Even earlier, cooking widened the range of available food species and therefore of habitats, its origins traceable to the use of the first stone cook's knife.

Cooking has often been depicted as part of women's housework, which supports "real" (male or public) production. It has belonged, as stated by Simone de Beauvoir in *The Second Sex*, to women's dreary sphere of "immanence" rather than men's artistic, intellectual world of "transcendence." This split helps explain why cooking has been little studied in any systematic way. Authorities are far from agreed on the basic cooking techniques, and words are used carelessly, such as "roasting" when "baking" is, in fact, meant. The central purpose of cooking has hardly been discussed, let alone settled.

Here cooking will be examined in the context of its narrow definition as heating. Then other techniques,

which include cutting, grinding, mixing, drying, fermenting, and attractive presentation, will be discussed. These techniques are grouped according to their broad outcomes, thus helping to identify cooking's cultural significance and social location. For further information on cooking's technical aspects, see particularly Harold McGee's *On Food and Cooking*; for information on its cultural and social aspects, see Michael Symons's *A History of Cooks and Cooking*.

### The Use of Heat

When Jean-Anthelme Brillat-Savarin assumed in *The Physiology of Taste* that the savory results of roasting derived from a juice in meat called "osmazome," his thinking was not all that unusual in the early nineteenth century. Later work has found instead that the pleasing taste results from a complicated set of changes produced through caramelization and the so-called Maillard browning reactions. Nonetheless, as Harold McGee argues in *The Curious Cook*, "Whatever it is about a roast that inspires such devotion deserves a name, and in the absence of a better one, osmazome serves admirably" (p. 296).

Roasting, baking, broiling, grilling, and frying reach the relatively high temperatures necessary for browning to be achieved sufficiently quickly. The relatively plain-looking and bland effects of boiling and steaming follow from their temperatures being limited to the boiling point of water, 212°F (100°C). Nevertheless, all heating methods alter the aroma, appearance, and texture of foods. Furthermore, heat can turn some otherwise poisonous or inedible substances into food, and change other nutritional properties, not always for the better.

The basic techniques of cooking (in the narrow sense) rely on the physicists' three modes of heat transfer—radiation, conduction, and convection. The glowing coals radiate at relatively high temperatures to roast a joint on the spit. When food is placed on a gridiron immediately over the radiant source, this is grilling. Broiling is similarly intense but from above. Energy is transferred to the food through conduction in the separate techniques of boiling, steaming, and frying. Gentle boiling (poaching or simmering) also relies on the circulation of heat through convection.

Practical methods combine all modes of energy transfer. In baking, the walls of the oven radiate heat, hot air moves through convection, and energy transfers through conduction. Nothing could seem more direct than roasting, until processes internal to the cooked article are considered, such as conduction of heat from the surface inward and steaming within the cavity of a fowl.

Cooking methods employ different mediums, most basically water, oil, or air. Food is boiled, poached, and steamed with water. Food is either deep-fried immersed in hot oil or shallow-fried on a layer of oil in a pan. Baking employs heated air. Again, practical methods combine mediums. An obvious example is braising, which

expressly relies on frying and then, after adding liquid and closing the lid, poaching and steaming in the same container.

The promotion of the “economy” stove by British Count Rumford (Benjamin Thompson) added to the confusion at the beginning of the nineteenth century, because he claimed to roast a joint in a “closed” oven, which both improved efficiency and kept flue gases separate. However, since oven temperatures were much lower than those emanating from open coals, his “roast dinner” was a misnomer. An equivalent twentieth-century misconception resulted with the microwave oven, which employs an entirely different science—the stimulated vibration of water molecules so that food heats up internally—so that the device is not really an “oven.”

According to the massive *Mrs. Beeton's Book of Household Management*, published in England in 1909, the six cooking methods “commonly spoken of” are roasting, boiling, broiling, frying, stewing, and baking. These are the same methods listed in the general prologue of the *Canterbury Tales* more than five centuries earlier, when Geoffrey Chaucer claimed the cook was able to “rooste, and sethe [boil], and broille, and frye, / Maken mortreux [stews], and wel bake a pye.” Although ten basic methods have already been discussed above—roasting, broiling, grilling, baking, boiling, steaming, shallow frying, deep frying, and microwaving—Chaucer reasonably distinguishes stewing from boiling, and many modern-day cooks would also regard poaching as distinct.

Claude Lévi-Strauss's much-reprinted but, for many people, puzzling “culinary triangle” had three cooking methods placed at each corner (boiled, roasted, and smoked). By then finding places for another three (broiled, fried, and braised), he again assumed a total of six methods. He omitted baking, however, and added smoking, although this sort of drying and light tarring might be better listed under preservation methods. Stir-frying deserves its own place of recognition, and so do infusion (as in preparing tea), steam extraction (as in espresso coffee), and pressure-cooking. And yet another complication in this attempt at categorization is the fact that rice largely “cooks” by absorption. In the end, any list of cooking methods remains merely indicative and conveys only broad principles.

### The Cooking Fire

Basic cooking (by heating) relies on various heat sources. Any list of principal cultural variants would have to include the spit, gridiron, grill (or salamander), boiling and stewing pot, enclosed braising pot, steamer, frying pan, stir-fry wok, deepfryer, vertical oven (*tannūr*), horizontal oven (baker's oven), range, and microwave oven. Some basic features can be demonstrated by discussing just four: the open fire, the stewing pot, the oven, and the brazier.

Although not necessarily the oldest method, the open roasting fire is primordially simple, with meat and

The most ancient images of cookery invariably depict women, since management of the hearth was one of the traditional domestic spheres assigned to females. This ancient Greek terracotta statuette from the third century B.C.E. depicts a woman cooking. © GIANNI DAGLI ORTI/CORBIS.

other foods skewered on vertical sticks or rotated horizontally on a spit. Roasting was first used by hunters, has often been called the *Homeric method* since its use is cited frequently in the ancient stories of Homer, and has held a particular appeal for the British in recent centuries.

Historically even more important than the spit is the stewing pot. In this vessel various ingredients are combined for long, slow heating; sometimes, the pot's contents are just continuously replenished over days and weeks. Pots have typically been made of clay but variations have included rock depressions (heated by hot stones), leather pouches, and, increasingly, metal containers. The pot was associated with the emergence of a settled society where it was used for both storage and the slow cooking generally required by storable crops.

Dedicated clay ovens are nearly as old as pots, dating from at least seven thousand years ago. These “vertical” ovens are most familiar to English speakers as tandoor ovens (from the Hindustani). Many similar words used in and around the Middle East derive from the ancient Persian, Arabic, and Hebrew *tannūr*. The classic version is a clay barrel containing the fire, entered from

the top; it is characteristically used for flatbread placed briefly on the wall inside, so that one side browns through conduction and the other through radiation. Throughout Europe, the more familiar variation of this kind of oven has been the horizontal (or “baker’s”) oven often used to make leavened bread and sharing the floor with its fire in the simplest versions.

The brazier is another simple pot of burning dung or charcoal, on which appropriate containers are placed so that food is broiled, fried, stewed, or baked. Relatively efficient, it has been used when fuel is scarce and so has remained extraordinarily widespread—as common in ancient Athens as it has remained throughout Asia. An enlarged brazier with two or more apertures for heat is the range, fueled by wood, coal, gas, or electricity.

Most major English language dictionaries agree on the definition of the verb “cook” as “to prepare (food) by heating it,” and the basic techniques and devices described here are commonly accepted. However, cooking plainly employs many other techniques. The development of artificial refrigeration in the nineteenth century only increased the importance of the removal of heat in certain preparations, such as freezing ice cream. Preparing mayonnaise, for instance, also involves combining oil and eggs entirely without heat.

Other important techniques will now be discussed under their broad outcomes, mainly shared by heating. For example, heat enhances pleasures, not merely taste but also texture by, among other methods, obtaining various concentrations of sugar syrup for soft fudges, firmer caramels, toffee, and spun sugar. Heating also supports two of cooking’s other broad purposes, improved nutritional qualities and storage. Heating contributes less noticeably to an additional, presumably underlying task, food distribution.

### Making Food Attractive

Cooks have become immensely skilled at enhancing the sensory appeal of food. Adding sugar, salt, and acid (such as vinegar) has a marked effect on flavor, although this might often be a side effect of some other desired outcome, such as preservation. Nonetheless, improved attractiveness has been the basic reason for many other simple additions, such as pepper, ginger, caraway seeds, mint, mustard, nutmeg, and vanilla. Spices typically modify aroma and taste, and sometimes they also impart a charming color, as with saffron. The English concept of “curry” does not do justice to the full range of spices ground and blended into much Indian cooking.

Subtly flavored sauces—the peak of grand French cooking—are classically based on stocks, made by simmering bones to extract gelatin (especially veal because younger bones are rich in gelatin-producing collagen). A brown stock flavored with red wine and shallots then becomes a *bordelaise* sauce, and so on. Other sauces are prepared by emulsification, in which oil is so finely dis-

persed in another liquid that it remains suspended. For instance, mayonnaise is oil dispersed in egg yolks. Flavored with garlic, mayonnaise becomes *aioli*. Other emulsions are made from butter and cooked egg, notably hollandaise and its derivatives, such as *béarnaise* with tarragon. McGee suggests that the “fragrant sauce” for asparagus in La Varenne’s cookbook of 1651 may be the first recorded recipe for an egg-based emulsified sauce.

The improvement in the organoleptic appeal of food—and sophisticated cooking involves much tasting and visual adjustment—has been viewed as the essential purpose of cooking by ascetics and hedonists alike. Vegetarians have historically said that good cooking is necessary to disguise meat so that eaters might overcome their disgust. Likewise, the ancient philosopher Plato condemned cooking as the seduction of palates away from higher pursuits. In response, hedonists, whether on a par with Brillat-Savarin or not, have viewed cooking as not the devil’s but God’s gift.

A modern interpretation of this subject recognizes that food’s attractiveness is for the most part socially conditioned, as proved by the wide variety of cultural taboos and preferences. Some groups, for instance, even embrace the poisonous reaction of chili. Thus, cooking does not enhance food’s intrinsic attractiveness so much as transform it into a cultural or social symbol. Food has been “good to think” as much as “good to eat” (to borrow again from Lévi-Strauss in *Totemism*). Elaborate French sauces are the unspoken language of opulence and “good taste,” haggis indicates Scottishness, red meat exhibits maleness, and the avoidance of pork suggests religious commitment.

Along these lines, cookbook writer Elisabeth Rozin has talked of cooking being responsible for distinct “flavor principles,” so that flavoring with soy sauce, garlic, brown sugar, sesame seeds, and chili, for example, identifies food as Korean. The Hungarian flavor principle is paprika, lard, and onions. In this way, cooking adds little national flags, so to speak. Such a system might even have a sound nutritional basis in that, as omnivores, humans rely on cultural markers for safe, balanced, or otherwise appropriate foods.

### Predigestion

Nutritionally, cooking is a kind of predigestion. Although cooking can reduce the nutritional value of raw foods, it may also make otherwise inedible foods accessible by releasing the nutritive parts of some foods and rendering others safe. Techniques include removing protective shells from seeds and nuts, physically softening or chemically tenderizing what would otherwise be unchewable, making certain nutrients more readily digestible, leaching out harmful compounds or inactivating them, and destroying troublesome bacteria.

Traditional cooks have gained impressively precise and presumably hard-won knowledge of how to handle

local species, such as the detoxification of older strains of manioc (or cassava). Even in the industrialized world, cooks know to peel potatoes that are turning green. Through nutritional improvements, cooking has widened the spectrum of available foods, thereby increasing human adaptability to habitats.

Just as significantly, cooking has enabled different modes of production. In his *Geist der Kochkunst*, Karl Friedrich von Rumohr recognized nearly two centuries ago that the development of human settlements and agriculture approximately ten thousand years earlier had relied on cereals not readily eaten in their original state. The same qualities that keep staples through the year tend to demand that they be processed, as when wheat is laboriously milled and then parched, boiled, or baked.

This ensured the necessity of another nutritional achievement of cooking, the provision of balanced meals. The typical cuisine of agrarian societies has two building blocks: the staple and its accompaniment, a relish or sauce. The main stored agricultural product, such as wheat, corn, and potatoes, is bland, starchy and nutritionally incomplete. The staple is enlivened and supplemented by an appropriate sauce made from a little meat (fished, hunted, or taken from the herd), an animal by-product (such as cheese), or a legume or vegetable.

The ancient Athenians, for example, based their meals on the *sitos* of barleycake and wheaten bread or perhaps lentil soup. The *opson* then provided extra proteins, vitamins, and interest, in the form of a salad of bitter herbs, cheese, eggs, fish (fresh, salted, or dried), or, less frequently, meat. Eventually, the desirable *opson* was fish. A gourmand was called an *opsophagos*, a topping- or sauce-eater.

As another example, Chinese cuisine divides a meal into *fan* and *ts'ai*. In a narrow sense, *fan* means “rice” or “cooked rice,” and *ts'ai* means “greens” or “vegetables.” In a broader sense, *fan* includes all cereal and starchy dishes, among them porridge, steamed bread, dumplings, pancakes, and noodles. And, *ts'ai* refers to the accompaniments, whether made of vegetables, meat, or fish. As explained by anthropologist Eugene Anderson and others, *fan* is “grain foods” and *ts'ai* “dishes to go on rice.” The two types of food have to be in balance, although more *fan* might be consumed at home and *ts'ai* dishes would be more numerous and prominent at feasts or on special occasions.

Although anthropologist Sidney Mintz has wanted to further divide agrarian cuisines into “core/fringe/legume,” nutritionist Daniela Schlettwein-Gsell finds enough nutritional wisdom in the typical combinations of “core” and “fringe,” as when wheat is complemented by leafy green vegetables. *Polenta con funghi* (cornmeal with mushrooms) exhibits a remarkably balanced nutrient density, as do the combinations involved in southern Italian pizza, Swiss raclette, Anglo-Indian kedgeree, North African couscous, Chilean empanadas, and so on.

## Storage

Settled society was made possible by stored food, which typically was not just cooked to be made edible, but often was also preserved in the first place. Preservation methods include drying, chilling, sugaring, salting, pickling, fermenting, and storing in sealed containers (often under fats and oils). They slow down deterioration by such means as removing moisture, altering acidity, and closing off oxygen. Cooking by heat has also played a role, killing microorganisms—bacteria, yeasts, and molds—that compete for the food, a process exploited in pasteurization.

Fermentation actually uses microorganisms in a controlled way to help convert raw materials into more stable forms, such as wine, beer, cheese, leavened bread, fish sauce, sauerkraut, and soy sauce. For example, in making wine, yeasts transform the sugars in grape juice into alcohol and carbon dioxide, until the yeasts have nothing to survive on. Cheese-making converts excess spring milk through lactic acid fermentation, during which the protein coagulates, and the solid mass can be retained because of its reduced moisture, together with extra saltiness and acidity.

Since the earliest division of labor between the sexes, women have generally been more intimately involved in cooking than men. However, baking, brewing, vinification, sauce-making, and the like have become important spin-offs of cooking performed by specialists, often (but not always) men. While the cooking of women has had a domestic focus (home and hearth), that of men is generally more public, or market-oriented. In recent centuries, food production has been rapidly industrialized, so that now much cooking, whatever its form, has been taken over by factories.

## Distributing

Meals are essentially sharing occasions and, in serving them, cooking should be seen as distributive at heart. Cooking employs a range of food-dividing techniques, including counting, weighing, and other forms of portion control. As Michael Symons has argued in *A History of Cooks and Cooking*, the most characteristic distributive activity has to be cutting, and the most obligatory distinctive culinary tool is the knife.

The classic American cookbook, *Joy of Cooking*, includes in its listing of essential kitchen equipment: two paring knives, one bread knife, one meat knife and grapefruit knife, along with such possible variants as spatula, two graters, wooden chopping bowl and chopper, meat grinder, doughnut cutter, biscuit cutter, pancake turner, apple corer, vegetable slicer or parer, can opener, and kitchen shears. These are used in peeling, coring, and chopping food into suitable pieces for cooking; they are also used to carve meat, slice bread, and cut out biscuits for all to share.

In Chinese cooking, the *tou* (cleaver) is employed to chop meat and vegetables. The quick stir-frying characteristic of this cuisine requires that the ingredients be cut

up into same-size, relatively small pieces. Nonetheless, the chopping and slicing also make the food highly distributive. The cleaver allows diners to put aside their knives and rely on chopsticks and spoons. Chinese observers have a point when they view the Western use of table knives as dangerous and barbaric, and cutting up as best left to preparation in the kitchen. The first sharp cutters, made specially from pebbles, date back to approximately two million years ago, which makes the cook's knife about twice as old as the cook's fire. The stone cutters used in scrounging and dividing up flesh heralded the "cooking animal," and innovations in knife-making technology contributed to the names of the Stone, Bronze, and Iron Ages.

The importance of sharing sustenance through meals gives the cutting or carving of foodstuffs and therefore kitchen knives a central place in human life. They are essentially generous instruments. However, the very success of cooks' knives has led to their being overlooked, because the division of food goes hand in hand with the division of labor. Meals are the mechanism by which people share not merely food, but also the associated tasks; everyone brings their contribution to the table.

Unfortunately, while the value and importance of cooking have not always been recognized, specialists have aggrandized their in many ways subsidiary trades and tools, as when men distributed meat through such rituals as temple sacrifice and courtly carving. The fundamental instruments of humankind's social interaction with nature, knives, have thus cut people off from each other and their world.

**CORN.** *See* Maize.

**COST OF FOOD.** The cost of food is viewed from two perspectives. One is the cost to households, the other is the cost of production and marketing. Since food is a basic necessity in every society, a falling portion of household income needed to purchase food is an indicator of growing households' incomes and a measure of improved national economic development. In high-income countries the percentage of income needed for food is smaller than in low-income countries. This phenomenon reflects an economic principle known as Engels' Law. As income rises, the percentage of the additional income spent on food declines.

#### Consumers' Food Costs

In the United States the percentage of personal disposable income (PDI) spent for food fell precipitously during the second half of the twentieth century from 20 percent in 1960 to 11 percent in 2000 (see Figure 1). At the beginning of the twenty-first century the United States had the lowest ratio of food expenditures to PDI in the world. Expenditures for food ingredients to cook at home fell in tandem with the decline in the percentage of income spent on all food. Expenditures on food

FIGURE 1

from restaurants and other food service places remained steady at around 4 to 5 percent of PDI in the late twentieth century. Consequently the percentage of households' total food budget spent for food service increased from 27 percent in 1960 to 47 percent in 2000.

Expenditures on food rise with income and the number of people in the household. The absolute amount spent on food rises with income as consumers shift to more expensive brands, higher-quality food, and more convenient forms of food, including more food eaten away from home. Households with only one person spend 16 percent more per person on food than households with two people and 62 percent more per person than households with four people. Per capita expenditures for food are greater for single people because of the economies of scale involved in feeding more people in the same household. With more people to feed, less waste occurs from preparing full recipes, and people are more inclined to

cook food at home. Single persons tend to eat more food away from home, increasing their food costs (Blisard, 2000, pp. 23–26).

Lower-income households spend about two-thirds the number of dollars per person on food compared with higher-income households and about 85 percent as much compared with middle-income households. Even though households in the lowest income group spend fewer dollars on food, these expenditures account for almost half of their incomes. Those in the highest-income group spend only 8 percent of their incomes on food. The average food expenditure, 11 percent of PDI, represents middle-income households and hides the fact that great disparity persists.

### Production and Marketing Costs

Production and marketing costs determine the minimum price of food in the retail marketplace. Production costs

are typically called the “farm value” of food, and they comprise about 20 percent of the final food cost. This percentage varies by type of food, depending on how highly processed or perishable the food is. The farm value for meats and dairy products is around 28 percent, for poultry around 41 percent, for cereals around 5 percent, for fresh fruits 16 percent, and for fresh vegetables 19 percent. As consumers demand more highly processed foods, fresh foods from distant places, and foods ready to eat, the farm value falls as a percentage of the retail price.

Marketing costs have risen as a percentage of retail food prices. The “marketing bill” as defined by the U.S. Department of Agriculture is the difference between the farm value of domestically produced foods and the final cost to the consumer (see Figure 2). Marketing costs rose 3.5 times faster than the farm value between 1990 and 1999. At 39 percent, labor is the largest portion of the cost of food, rising 56 percent during the 1990s. Over half of the 14 million food industry workers in 1999 were in food service. Retail food stores employed 3.5 million or about one-fourth of all food industry workers. About 12 percent of food industry employees worked in food processing, and about 7 percent worked in food wholesaling. The escalating demand for labor increased wages and the benefit costs for food workers. Food store employees’ wages rose 27 percent during the last decade of the twentieth century. As consumers delegate more of the basic cooking and preparation of food to others in the food chain, labor costs can be expected to rise as a portion of the total food cost.

Packaging costs comprise about 8 percent of total food costs, and they increased almost 40 percent in the 1990s. This increase is a function of the cost of paper and plastics and the demand for more conveniently packaged foods. Package design changes and packages that can be used directly for cooking and for eating or drinking increase the cost of packaging relative to the basic food.

Raw commodities (farm value), labor, and packaging comprise 67 percent of the cost of food. The rest of the costs are in transportation, advertising, rent, profits, energy, business taxes, depreciation, interest payments, miscellaneous costs, and repairs. These last types of costs have increased at about the rate of inflation and have not changed their share of the food dollar much over time.

Since considerable price competition exists at the retail end of the food chain, the marketing chain tends to absorb increases in the cost of raw commodities. Also the cost of the raw commodity is a relatively small percentage of the total cost. In the case of cereals, cyclical fluctuations in grain prices barely affect the final food price. One way for manufacturers to decrease their risks of price fluctuations in raw materials is to contract with farmers for a set amount of commodity at a set price that does not change at the whims of the market.

Retail food costs are a function of the production and marketing costs and the intersection of supply and demand. Since most foods have a limited shelf life, retailers want to sell products as soon as possible, keeping prices competitive. On the other hand, total food

FIGURE 2

expenditures are a relatively small part of most consumers' budgets, and an increase in the price of one food type does not change spending patterns much in the face of numerous substitutes. Taken together these two impacts are called the price and income effects on the quantity of food purchased. The other effect is the limited capacity of human beings to consume food. Once humans are physically satiated, food expenditures rise due to consumers' demands for more quality, variety, convenience, and service but not for more food to eat.

**COUSCOUS.** Couscous (from the Berber word *k'seksu*) is the staple product of North Africa and the national dish of the countries of Maghrib, that is, Algeria, Morocco, and Tunisia. Couscous spread from this area, where it originated, to Libya, Mauritania, Egypt, and sub-Saharan countries. Couscous is also consumed in the Middle East, where it is called *mughrabiyya*.

Couscous is an icon food in northern Africa for dietary and cultural reasons. Similar to rice, pasta, or bread, couscous is an inexpensive and highly nutritive product made from wheat or other cereals (barley, sorghum, corn, millet, or minor grains) with the capacity for long-term preservation. With a basic cooking system, it is possible to prepare an everyday meal or a luxury feast, a main course or a dessert. A versatile dish, couscous can be mixed with vegetables, legumes, meat, or fish, or it can be eaten with butter or fresh fruit.

Couscous is an icon also because it permits the expression of national identities and ways of life, and it has religious and symbolic meanings. Women usually prepare the grain known as couscous during a family celebration, and the dish named couscous is eaten during a family feast, thereby associating both the product and the dish with solidarity. Couscous accompanies Friday and end of Ramadan celebrations and birth and wedding feasts. The association of couscous with these festivities also attaches it to the concepts of abundance, fertility, fi-

delity, and Barakah (God's blessing). For example, while preparing couscous, women have to make an invocation and converse about religious facts, prosperity, and positive feelings.

#### Preparation

**The grain.** Although the use of precooked couscous has spread widely, making couscous is traditionally a female activity that involves much work. On a big flat plate, the woman in charge puts a handful of freshly ground hard wheat, sprinkles on salted water and a bit of flour, and with her palms treats the grain with rolling movements until the couscous granules appear. Later she sifts the grain with sieves of different diameters to obtain granules of similar size. Finally, couscous is sun-dried and stored or cooked.

**The dish.** Couscous is cooked in a special pot (a couscous steamer), usually earthen, which has two components: a bottom-perforated pan, which contains the grain, and a globular pot that stands underneath it and contains water or a boiling stew whose steam cooks the granules.

Moroccan waiter with a large platter of couscous in Marrakesh.  
© ROBERT HOLMES/CORBIS.

Couscous is moistened with water and oil before cooking and then it is placed in the pan. Every ten or fifteen minutes, the couscous is taken out of the pan; oil or butter is added, and it is worked by hand to avoid the formation of curds. Couscous is ready when the granules are cooked, separated, soft, and moist.

The basic ingredients of the couscous stew are seasonal vegetables and legumes (usually chickpeas), fish or meat (chicken, lamb, beef, rabbit, hare, and even camel), and spices. There are regional preferences regarding couscous. Algerian couscous includes tomatoes and a great variety of legumes and vegetables, and Moroccan couscous uses saffron. Tunisian couscous includes fish and dried fruit recipes and always contains chickpeas and a hot salsa (*harissa*). Saharan couscous is served without legumes and without broth.

After the grain is cooked, a pile of couscous is placed in a big platter topped with the meat or fish and vegetables. The couscous broth is put in a side bowl and optionally mixed with hot sauce.

### The History of Couscous

**Origins.** The origin of couscous is uncertain. Lucie Bolens affirms that Berbers were preparing couscous as early as 238 to 149 B.C.E. (Bolens, 1989, p. 61). Nevertheless, Charles Perry states that couscous originated between the end of the Zirid dynasty and the rise of the Almohadian dynasty between the eleventh and the thirteenth centuries (Perry, 1990, p. 177).

**Iberian Peninsula.** Bolens dates the introduction of couscous into the Iberian Peninsula to the period of the Berber dynasties in the thirteenth century (Bolens, 1989, p. 62). The popularity of couscous spread quickly among the Moors, and the two Arab cookbooks available from that time, the anonymous *Kitâb al Tabij* and *Fadilat al Jiwân* by Ibn Razîn al Tujibî, include couscous recipes. Sephardim incorporated couscous into their cuisine because of the Moorish influence and carried it to their asylum countries after their expulsion from Iberian lands (1492). It is still popularly consumed in Israel.

Couscous also was a staple for the Moriscos, who ate it during secular and religious celebrations. Consequently, the Inquisition prosecuted its consumption. The hostility toward Morisco culture and foodways led to the disappearance of *alcuzcuz* from Spain and to the development of a derivative, *migas*. In Portugal the gentry and nobility still consumed couscous during the sixteenth and seventeenth centuries; however, the *cozido à Madeirense* (a couscous dish) has its origin in African influences. According to Francisco Abad, the couscous recipes included in the Spanish court cookbook by Martínez de Montañón (seventeenth century) are related to the author's Portuguese origin (Abad, 2000, pp. 23–24).

**Italy.** *Cuscusu* is a typical dish of western Sicily, especially of Trapani, where it is eaten with a fish stew or in

a sweet recipe. There is no agreement about the date of the introduction of couscous into Sicily. Some writers claim that couscous was introduced during the Muslim period (827–1063), while others state that it was introduced after the settlement of Sephardim in the island, at the end of the fifteenth century.

**Brazil.** The introduction of couscous into Brazil in the sixteenth century, according to Luís da Câmara Cascudo, was a result of the culinary influences of both Portugal and African slaves cultures (Cascudo, 1983, pp. 207–211). There are two varieties. Southern couscous (*Cuscuz paulista*) is a steamed cake made from corn flour, vegetables, spices, chicken, or fish (prawns and sardines). The northern variety (*cuscuz nordestino*) is a steamed pudding made from tapioca flour and sugar and moistened with coconut milk. This is a popular Brazilian breakfast.

### Couscous in the Western World

Couscous has developed worldwide popularity. Among the explanations for its success are the increasing importance of vegetarianism, the preference for healthy foods that are aesthetically attractive, the trendy fascination with the Mediterranean cuisine, and the culinary influence of Maghribian immigrants in the Western world.

**CROP IMPROVEMENT.** Crop improvement refers to the genetic alteration of plants to satisfy human needs. In prehistory, human forebears in various parts of the world brought into cultivation a few hundred species from the hundreds of thousands available. In the process

they transformed elements of these species into crops through genetic alterations that involved conscious and unconscious selection, the differential reproduction of variants. Through a long history of trial and error, a relatively few plant species have become the mainstay of agriculture and thus the world's food supply. This process of domestication involved the identification of certain useful wild species combined with a process of selection that brought about changes in appearance, quality, and productivity. The exact details of the process that altered the major crops is not fully understood, but it is clear that the genetic changes were enormous in many cases. In fact some crop plants have been so changed that for many of them, maize, for example, their origins are obscure, with no extant close wild relatives.

The selection process was unconscious in many cases. For example, in wild wheats, the grains scatter by disarticulation, separation of the seed from the seed head. When these grains were harvested by cutting the heads with a sickle, an unconscious selection occurred for "non-shattering" types that would then be continually replanted. For some crops a clear conscious selection occurred, especially when the variant was obvious and would be maintained by vegetative propagation. Something so clearly useful as a seedless banana must have been immediately seized upon and maintained ("fixed") by planting offshoots of the plant. The changes wrought in domestication included alteration in organ size and shape; loss of many survival characters, such as bitter or toxic substances; disarticulation of seeds in grains; protective structures, such as spines and thorns; seed dormancy; and change in life span—increased in crops grown for roots or tubers and decreased in crops grown for seed or fruit. Selection by bulking desirable types (mass selection) is a powerful technique for making rapid changes easily while maintaining genetic diversity in the population.

The selection of naturally occurring variants is the basis of crop improvement. Over thousands of years this technique resulted in the development of modern basic crops. The discovery of techniques for asexual (vegetative) propagation, such as by using natural offshoots, rooting stem cuttings, or various grafting techniques, made it possible to "fix" genetic variants. This was the technique used for many tree fruits, enabling identical plants to be cultivated in orchards. Naturally produced seedlings derived from intercrosses of these selected plants were then available for selection again. Many present-day fruit crops are similar to those cultivated in antiquity, and some ancient selections are still cultivated—dates, for example. As humans carried improved crops to new locations, opportunities opened to increase genetic variation from natural intercrosses with new wild populations.

The changes that occur can be dramatic over time, as seen in the proliferation of breeds of animals and especially the wide range of changes brought about by fanciers of dogs, chickens, and pigeons. The observation

of these changes influenced the thinking of Charles Darwin to suggest that natural selection, the survival of the fittest, could lead to enormous genetic changes if carried out over a long enough time, and could lead to the origin of new species.

In the eighteenth and nineteenth centuries a conscious attempt was made to predict the performance of plants that could be expected from one seed generation to the next. The concept that ancestry was important in crop improvement led to refinement in the selection process, brought about by keeping records and the assessment of lineage. Furthermore it became obvious that variation could be managed by controlling the mating process, an extension of what had long been known in animal breeding. This new type of selection, termed pedigree selection, was found to increase the efficiency of the process. Progeny testing (evaluating the genetic worth by progeny performance) increased efficiency of this process. The origins of commercial plant breeding began in the second half of the nineteenth century among seed producers. It involved controlled crosses (hybridization) between selections to control genetic recombination, followed by selection of improved types. This is still the basis of traditional plant breeding. Interestingly much of this early type of plant breeding was carried out without a clear understanding of the genetic mechanism involved in inheritance.

Until the famous experiments with the garden pea by Gregor Mendel (1822–1884), a Catholic priest in Brünn, a Moravian town then in the Austro-Hungarian Empire, the basic theory of inheritance involved the concept of blending. Mendel unraveled the basic concept of inheritance and clearly showed that characters in the pea were due to elements, later called genes, that remained unaltered as they were inherited. Many characters in peas, such as tallness and dwarfness, were shown to be controlled by a pair of genes, of which one member was not always expressed (the concept of dominance and recessiveness). Mendel demonstrated that the gametes of the pea contained one member of the gene pairs that controlled characters and that recombined randomly at fertilization. Mendel's paper was published in 1866, but it had no impact until the paper was "rediscovered" in 1900, when it created a sensation. It was soon obvious that the differences in appearance among plants (phenotypes) could be explained by the interaction of various genes (genotypes) as well as interaction with the environment.

### Twentieth-Century Developments

In the twentieth century plant breeding developed a scientific basis, and crop improvement was understood to be brought about by achieving favorable accumulations and combinations of genes. Taking advantage of known genetic diversity could facilitate this, and appropriate combinations were achieved through recombinations brought about by the sexual process (hybridization). Furthermore it was possible to move useful genes by special

breeding strategies. Thus a gene discovered in a wild plant could be transferred to a suitable adapted type by a technique known as the backcross method. A sexual hybrid was made, followed by a series of backcrosses to the desirable (recurrent) parent, while selecting for the new gene in each generation. After about five or six backcrosses, the offspring resembled the recurrent parent but contained the selected gene.

In the early twentieth century it was demonstrated that the extra vigor long associated with wide crosses (called hybrid vigor or heterosis), particularly in naturally cross-pollinated crops, could be exploited in plant breeding. For maize, a new system of hybrid breeding was developed, using a combination of inbreeding and outbreeding. Inbreeding was accomplished by crossing the plant with itself. This led to a decline in vigor as the step was repeated over several generations. Outbreeding was achieved by intercrossing the inbred lines to restore vigor. The hybrid between inbreds derived from divergent inbreds (called a single cross or  $F_1$  hybrid) was uniform (homogeneous), and some were superior to the original populations before inbreeding. During the process of inbreeding, the inbreds became weak, but vigor was restored in the  $F_1$ . To increase seed set from weak inbreds, two hybrids were crossed; this was known as the double cross method.

Hybrid breeding technique in a sense is similar to arranging a Rubik's cube, where contradictory steps need to be taken to achieve the appropriate reformulation. In hybrid breeding, the first step produces a series of weak inbreds, followed by a series of specific combination, to produce a series of new hybrids. Hybrid maize breeding led to enormous increases in productivity, which were soon exploited in a wide variety of seed-propagated crops, including naturally self-pollinated ones, such as tomato and rice.

A number of genetic techniques were developed and refined in twentieth-century breeding, such as improved techniques to search for and store increased genetic variability, different techniques to develop variable populations for selection, and improved methods of testing to separate genetic from environmental effects. The exact details of the process for crops necessarily differed among naturally cross-pollinated plants (such as maize) and naturally self-pollinated plants (such as soybean or tomato) as well as those plants in which vegetative propagation (usually cross-pollinated) permitted the fixing of improved types directly.

Conventional plant breeding can be defined as systems for selection of superior genotypes from genetically variable populations derived from sexual recombination. The system is powerful because it is evolutionary; progress can be cumulative, with improved individuals continually serving as parents for subsequent cycles of breeding. Genetic improvement by conventional breeding has made substantial changes when the efforts have

been long-term. Characters improved include productivity, quality, and resistance to diseases, insects, and stress. There are, however, limits to the progress of conventional breeding. These are due to limitations of the sexual system, because it is usually not possible to incorporate genes from nonrelated species or to incorporate small changes without disturbing the particular combination of genes that make a particular type unique. Thus a useful gene in cabbage cannot be transferred to wheat. Limitations of conventional breeding are particularly apparent when a needed character (such as disease or insect resistance) is unavailable in populations that can be incorporated by sexual crosses. Mutations may be induced, but they are often deleterious or connected with undesirable effects.

With conventional breeding, it is also not possible to improve a unique genotype, such as "Bartlett" pear, by adding a single character, since the recombination that results from hybridization makes it impossible to reconfigure this cultivar exactly. Finally, conventional breeding has technical or economic limitations to detect infrequent or rare recombinants, the lack of sufficient time to generate cycles of recombination, space to grow necessary populations to recover superior recombinants, or resources to be able to select, identify, evaluate, and fix desired recombinants.

### Developments Using DNA

It has been suggested that many of the limitations of conventional breeding can be overcome with advances in molecular biology that rely on DNA, the genetic material.

Recombinant DNA technology, called transgene technology or genetic engineering, is the most powerful and revolutionary of the new genetics developed in the last half of the twentieth century. It is possible to isolate stretches of DNA from one organism, store it in a bacterial host, select unique combinations, and then incorporate them into the DNA of another species, where it can be expressed. This technique, which relies on cell and tissue culture, is truly a marvelous process. Refinements in the technique make it possible to concentrate mutations in desired genes, further increasing variability. Other uses of molecular biology known as genomics involve the detailed mapping of the DNA and the identification of useful stretches of the molecule. This makes it possible to improve the efficiency of selection, because it is based directly on the genes rather than the organism, where the effects may be confounded by environment and genetic interactions.

The limitations of the new breeding methods include technical problems, such as the difficulty of transformation, problems of gene expression, or the lack of knowledge concerning suitable genes to transfer. There are also nontechnical issues, such as legal problems, since the techniques and the genes are usually patented. However, in the short run the greatest impediment has been problems of consumer acceptability and fear of the unknown.

The term “Frankenfood” has been coined to refer to food altered by the process of using exotic genes incorporated by transgene technology. No convincing evidence shows that genetic engineering has produced harmful products, and an abundance of evidence shows that many foods derived from traditional systems have inherent problems (consider the allergic reactions of many people to peanuts). Nevertheless, molecular techniques have incited fear of this new technology in many people. Moreover, the surplus of food in the West has reduced the imperative to make the case for the need for new technology to consumers.

The biotechnology industry has sold the technology to farmers (who have accepted it) and ignored consumers. They have not been sophisticated in exploiting the environmental virtues inherent in the new technology, such as reducing pesticides, or in making the case that increased yield could free up the agricultural use of fragile environments. Because of the benefits that could accrue from this new technology, especially in the problem areas of the world, it seems certain that future progress in plant breeding will involve both conventional and unconventional techniques, but the immediate course of events is fraught with uncertainty.

**CRUCIFER PLANTS.** See **Cabbage and Crucifer Plants.**

**CRUSHING.** Crushing refers to the pressing, grinding, or pounding of an item into smaller particles, a powder, or a paste. The largest of the human teeth, the molars, are designed for crushing food into small particles that can be swallowed and digested. Digestion is enhanced by the breaking of food into small particles that expose more food surface to the action of digestive enzymes; the more food surface exposed, the more efficient the process of digestion.

The crushing of cereal grains (wheat, corn, rye, buckwheat, rice) into flour is a good example of the use of tools to reduce particle size. The flour can then be eaten raw, cooked with water into porridge, or moistened, formed into a loaf, and baked as bread. Another

nutritional advantage of flour over the whole grain is that the flour can be sifted to remove the bran fraction, which is largely cellulose and indigestible. The germ fraction of the kernel is typically removed with the bran and hence considerably reduces the nutritional values of the flour in terms of protein, vitamins, and minerals. Flours, rather than whole grains, also have the advantage of cooking faster and can be used to make gruels that are useful for feeding infants and the elderly, who have a limited ability to chew foods into small particles.

A number of devices have been used to crush grains into flours. The Australian Aborigines used a simple wooden mortar and stone pestle to roughly crush grass seed, which they used to make bread, or *dampier*. The ancient Egyptians developed a mill made of two circular stones to crush wheat into flour; modern mills operate on the same principle. Traditional peoples in Mesoamerica used a stone mortar and pestle to crush presoaked corn kernels into a wet mash to make tortillas. Foods with hard, inedible shells are crushed to facilitate removal of the shell and extraction of the edible component. Examples are hard-shelled nuts like walnuts and shellfish like lobsters. The devices used are tools like hammer-stones and metal pliers.

Other foods are crushed to extract a component of the food from the more fibrous matrix of the whole food. Seeds and palm fruits are crushed to extract the oil. Grapes and other soft fruits, as well as sugarcane, a tall grass, are crushed to extract the juice. Oils and juice tend to be more readily digested than the whole food. Also, the liquid can be added to other foods to improve their energy content and hence the energy content of the diet. This is especially important in rootcrop- and tuber-based diets, which are typically low in energy density.

Many foods are prepared or processed by crushing. This first-century C.E. Roman bas-relief depicts men crushing grapes for wine. © ARCHIVO ICONOGRAFICO, S.A./CORBIS.

The tools used in crushing foods vary with the foods themselves and level of technology. Grapes are crushed gently to avoid damaging the seed that can release bitterness into the wine. They were traditionally crushed by workers' treading on them or with wooden paddles. Olives are crushed to separate the pit from the pulp and the latter then pressed to extract the liquids. For the initial step the Romans used a roller-mill (*trapeta*), designed to ensure that the olive pit itself would not be damaged. Sugarcane was crushed historically in South America by squeezing the cane through a set of rollers (*trapicbe*). The juice was then boiled to evaporate the water and the concentrated sugar allowed to crystallize.

Still other foods are crushed to achieve a particular texture in the preparation of certain dishes. In Hawaii, cooked taro corms (enlarged portion of the plant stem) are crushed to a smooth paste and then pounded in a mortar and pestle to make the famous *poi*. In Africa, cassava roots are left to soak and ferment in water and then crushed into dough that is molded into loaves and sun dried. Cooked yams are crushed with water to form soft dough called *fufu* in Ghana. In the highlands of Peru cooked potatoes are crushed on a grinding stone and then added to water or broth to make a thick soup or *masamora*. In Europe and North America, cooked potatoes are crushed to a soft uniform mass to make mashed potatoes. Nuts and meat are crushed into pastes to make sandwich spreads like peanut butter and potted meats or pâté.

In a number of different cuisines, spices are crushed to stimulate the release of flavor. In India, spices are ground in a mortar and pestle. In Mexico, spices were traditionally crushed to a paste with chili peppers using the same grinding stone (*mano* and *metate*) used for grinding maize, or in a stone bowl made from lava stone. Garlic, a flavoring agent, is also often crushed before being added to food. In all cases flavor enhancement and flavor release are the goals of the cook, but the crushing should also facilitate digestion.

Crushing is also used to meld two or more foods together. A classic example is the pemmican traditionally made by North American Indians. Pemmican is dried meat and animal fat pounded into a paste and preserved in the form of pressed cakes. A less well-known example is "desert fruitcake," a cake made of crickets pounded together with berries. Another example is *kibbeh*, a Lebanese dish made by pounding lamb and cracked wheat together in a stone mortar until they form a paste and seasoning the mix with mint and pine nuts. The resulting mix is rolled into sausage-like forms and cooked in oil or eaten raw.

**CRUSTACEANS AND SHELLFISH.** The crustaceans are not, strictly speaking, shellfish, although they are often described as such. They are members of the animal phylum Arthropoda, which also includes spiders, scorpions, and insects. Like these other creatures they are covered with hard, horny carapaces which are jointed for movement and sloughed from time to time as their owners grow. Many have a characteristic change of color when cooked, for example the blue-black lobster turns scarlet and the semitransparent shrimp turns pink and white.

The two principal orders are Decapoda Natantia and Decapoda Reptantia, that is to say, "ten-legged swimmers" and "ten-legged crawlers." In the first category are prawns, shrimp, lobster, and so on. The second consists of the crabs.

#### Prawns and Shrimp

The terms "prawn" and "shrimp" require a little explanation since the two terms are used in different ways in British and American English. The FAO (Food and Agriculture Organization of the United Nations) in their comprehensive *Catalogue of Shrimps and Prawns of the World* (1980), describes the differences in usage as follows:

we may say that in Britain the term 'shrimp' is the more general of the two, and is the only term used for *Crangonidae* and most smaller species. 'Prawn' is the more special of the two names, being used solely for *Palaemonidae* and larger forms, never for the very small ones. In North America the name 'prawn' is practically obsolete and is almost entirely replaced by the word 'shrimp' (used for even the largest species, which may be called 'jumbo shrimp'). If the word 'prawn' is used at all in America it is attached to small species.

The smallest shrimp are of considerable interest in regions such as Southeast Asia where they are eagerly collected to be fermented and made into shrimp paste, most notably in the Philippines, where it is known as *patis*, and also Malaysia and Indonesia, where it is *blachan*. Use of these products is less widespread than the ubiquitous

Southeast Asian fish sauces, but they too make a significant contribution to the diet in the countries where they are made. In Europe, especially Britain, small shrimp may also be made into a paste, but without fermentation and packed in small jars as a delicacy for the tea table. Delicate shrimp paste sandwiches are considered a real treat. It is also possible in England to buy potted (cooked and packed in butter) shrimps from Morecambe Bay, a traditional preparation which has cultural overtones, being perceived as part of the British culinary heritage and identity. In North America the very smallest shrimps attract little interest, and it is the larger species such as the brown shrimp (*Penaeus aztecus aztecus*) and the white shrimp (*Penaeus setiferus*) which are most prominent in the markets. In Europe, the counterpart of these species is the so-called deep water prawn (also known as northern prawn, *Pandalus borealis*; but this is not exclusive to Europe, being found also in the North Atlantic from Greenland down to Martha's Vineyard).

Large shrimp, especially species of the genus *Macrobrachium* which thrive in brackish or fresh water, are now the subject of aquaculture in Southeast Asia, and the large quantities exported from there go a long way to meeting demand in Europe. Large shrimp are often presented on their own (for example boiled and then served cold with mayonnaise, or broiled), while smaller ones may be used to make the shrimp croquettes which are a particularly successful dish in the Netherlands and Belgium, or a shrimp sauce or shrimp soup.

Large shrimp in the Mediterranean belong to various species which resemble each other so closely that sometimes it is only an expert who can distinguish between them. One of the best is *Penaeus kerathurus*, the Italian *mazzancolla*. It may reach a length of 22 cm/9 inches, which is large for the Mediterranean but well short of 33 cm/13 inches, the maximum length of the Giant Tiger prawn of the Indo-Pacific, *Penaeus monodon*.

## Lobsters

Lobsters are larger creatures, although the smallest of the the so-called Norway lobsters (often referred to by the Italian name *scampi*), are no bigger than the largest prawns. The archetypal lobster, that of the North Atlantic, is not one but two species, having developed in slightly different forms on the two sides of the ocean. The American lobster, *Homarus americanus*, attains a somewhat greater size than its European counterpart, *H. gammarus*. However, the whole question of maximum sizes has become one where precision is difficult to attain. The fishery for lobsters is now so intensive that few or none approach the maximum size recorded in the past. It is generally accepted that a specimen taken off the coast of Virginia in the 1930s holds the record; it measured more than a meter (3' 3") in length and weighed about 20 kg/45 lb. No lobster of comparable size has been taken since World War II. In any case, there is no special merit, for consumers, in great size.

FIG. 552. CRAYFISH SERVED EN BUISSON.

Lithograph showing crayfish *en buisson* arranged to resemble a cascade. From Theodore Garrett's *Encyclopedia of Practical Cookery* (London, ca. 1890). ROUGHWOOD COLLECTION.

The value of lobsters in the market is considerable, but the supply of adult lobsters from the wild is limited. One reason is that only certain types of seabed are suited to tiny postlarval lobsters. If they don't make it to a suitable place, they perish. Also, competition among lobster fishermen is intense. So, as long ago as the beginning of the twentieth century experimental lobster "farming" was being conducted in a number of countries.

Where lobsters are "farmed," one procedure is to raise them from fertilized eggs, keeping each tiny creature in its own compartment to prevent it from being eaten, and then releasing them into the wild when they are large enough to have a good chance of survival before they reach the minimum weight at which it becomes legal to catch them. This is generally around 450 to 500 grams (just over a pound). The alternative procedure involves keeping the lobsters in captivity until ready for sale. One advantage of this is that the fully "farmed" lobster may be sent to market at a weight of only about 250 g (half a pound) and will have attained that weight relatively quickly (further growth being slower). There is a large and growing literature on all this, whether conducted by institutions to increase stocks in the wild for the general benefit or by private "farmers" for their own profit.

The red color of a cooked lobster is intense and dramatic; it has been compared to that of a cardinal's hat. However, this cannot rival the amazingly bright and com-

Silver stand (*buisson*) for serving crayfish *en buisson*. France, ca. 1845. Poached crayfish were hung by their tails from the teeth around the rim of each tier, thus creating a cascade of crayfish, truffles, and parsley. ROUGHWOOD COLLECTION. PHOTO CHEW & COMPANY.

plex colorations of the “spiny lobsters,” also known as crawfish, which belong to warmer and tropical waters. Lobsters in this other category are, some would say, not true lobsters. They lack the large claws of the Atlantic species, and hence have less meat, but they grow to a good size and are greatly appreciated as food. They too are “farmed,” on an increasing scale. *Palinurus elephas* is one of several species that are present in the Mediterranean, while *Panulirus argus* is the most prominent in American waters. (The designations are confusing. The genus *Palinurus* has been recognized since the late eighteenth century, but it seems not to have occurred to the naturalist who created *Panulirus* halfway through the nineteenth century that he was sowing seeds of confusion by his choice of name.) The spiny lobsters of Asian waters include the remarkably beautiful *Panulirus ornatus* and *P. versicolor* (see illustration).

There are other “lobsters,” of different shape, classified in the family Scyllaridae and going by names such as “flat lobster” and “slipper lobster.” One, *Thenus orientalis*, has achieved fame and a certain cultural status in

Australia, where it is the “Moreton Bay bug,” a name which combines an Australian geographical identifier with an indication of Australian plebeian insouciance.

### Crabs

Most Europeans, invited to think of a crab, would have a mental picture of *Cancer pagurus*, the common crab of European temperate waters. North Americans would picture the famed blue crab of Chesapeake Bay and other parts of the eastern seaboard; or, if belonging to the western coast, the Dungeness crab. These three important species all share the familiar, compact, wide-bodied and big-clawed shape, and all are excellent tasting. The blue crab is, at least for east coast Americans, a cultural as well as a gastronomic phenomenon. The annual crab-picking “derby” at Crisfield, Maryland, is a symptom of its status. However, its reputation rests more on the fact that it is the crab which, when it has moulted and before the new hard carapace is grown, provides the basis for the soft-shell crab industry.

In waters that are either much colder or much warmer, crabs take on a different aspect. In the icy waters of the Arctic there is a vigorous fishery for two kinds of crab with extraordinarily long and thin legs, the snow crabs of the genus *Chionoectes* and the king (or red) crab *Paralithodes camtschatica*. Their meat, which is of excellent quality, is usually frozen or canned, since the fishing grounds are so remote that it would be impracticable to do otherwise.

In tropical waters, on the other hand, there is a great diversity of swimming crabs and others, often brightly colored. Some spend some time on land, for example the large land crabs that are appreciated in the francophone West Indies and, in the Indo-Pacific region, the red crabs of Christmas Island and the robber crabs, which climb coconut trees and steal the nuts.

### Crayfish

Although most edible crustaceans come from the sea, there are two important freshwater families, those of the crayfish (the family *Astacidae* in the northern hemisphere, and *Parastacidae* in the southern hemisphere). One interesting feature of the whole group of crayfish is that their distribution in the world is surprisingly, one might almost say inexplicably, patchy. Except for Papua New Guinea, there are none in the tropics. They are absent from most of Asia and are only found in two habitats in South America, yet there are over 250 species in North America. Europe has seven species and East Asia has four. Of the 120 species in the Southern Hemisphere, 110 are Australasian. They all resemble each other quite closely, but vary considerably in size and edibility. The largest is the giant Tasmanian crayfish, which may be 60 cm (two feet) from head to tail and may weigh as much as 4.5 kg (10 lb). Others are so small (2 cm /  $\frac{3}{4}$  inch) in length that they are of no interest except perhaps as bait.

A chowder party on Fire Island. From *Harper's Weekly*, 23 August 1873. ROUGHWOOD COLLECTION.

Habitats vary. There are aquatic crayfish living in rivers or streams; semiaquatic species that live out of water in burrows connected by shafts to a body of water; and the tiny land crayfish, which live on land but only on land that has water underneath it.

Enthusiasm for crayfish is greatest in Scandinavia, France, and Australia, but nonexistent in many places where they can be found. In North America crayfish used to be a delicacy exclusive to Louisiana (where they are called “crawfish”), but appreciation of it has for some time been spreading.

The European crayfish *Astacus fluviatilis* was wiped out in many European countries early in the twentieth century. A species from North America was introduced to important crayfish regions, notably Sweden, as a replacement. Crayfish have considerable importance in the culture of Scandinavian countries, and there are many rules of procedure involved in a crayfish feast, for example, wearing huge napkins round the neck, sucking at the carapace, etc. This applies generally in countries such as Finland and Sweden, where enthusiasm is at its peak. This enthusiasm is sometimes puzzling to people from other regions, given the small amount of nourishment to be had from one small crayfish and the considerable effort and skill required to extract it. However, there are two kinds of crayfish in Australia, besides the Tasmanian one

already mentioned, which are large enough to be eaten with less difficulty: the yabby (not a single species but several in the genus *Cherax*) and the marron (another *Cherax* species), which belongs to western Australia and is the third largest crayfish in the world.

To avoid confusion, it is well to note that the word crayfish is properly applied to the species described above, while the word crawfish is normally used to refer to spiny lobsters.

### An Oddball

One of the most delicious crustaceans has an appearance that resembles no other crustacean and does not suggest edibility. Moreover it is immobile and has a limited distribution centred on the Iberian Peninsula, to the cultural identity of which it makes a contribution. This strange creature is the goose-necked barnacle, *Mitella cornucopia*, best known under its Spanish name, *percebe*. It looks something like a rubbery, scaly tube with a hoof on the end. To eat it, one must prise off the outer tube, exposing a stalklike protuberance which may be bitten off entire. It is usual to boil the creatures briefly before serving them, but they can be eaten raw. It is in Spain and Portugal that *percebes* are most appreciated. They are costly, since gathering them from the rocks, at the foot of cliffs, to which they are typically attached, is often

difficult and sometimes dangerous. A larger relation, *Megabalanus psittacus*, is found on the west coast of South America and is eaten with enthusiasm in Chile.

**CUCUMBERS, MELONS, AND OTHER CUCURBITS.** Watermelon (*Citrullus lanatus*), cucumber (*Cucumis sativus*), and melon (*Cucumis melo*) are major crop species in the cucurbit or vine-crop family (the Cucurbitaceae), an important family of flowering plants (the angiosperms). The family also includes squash, pumpkin, and gourds.

Cucumber, melon, and watermelon are originally from the Old World (primarily Africa and Asia). Although they are in the same family (Cucurbitaceae) with the squashes, pumpkins, and gourds (mostly of the genus *Cucurbita*), they are only distantly related. The *Cucurbita* species are from the New World (primarily Central and South America).

Watermelon, cucumber, and melon plants are trailing or vining, tendril-bearing, frost-sensitive annuals. They are mostly monoecious (separate staminate and pistillate flowers, sometimes referred to as male and female flowers) and require various insects, especially bees, to effect pollination. The fruits are variously shaped, multiseeded, specialized berries called pepos. Together, plants in this family are called cucurbits.

**Watermelon (*Citrullus lanatus*)**

Watermelon is originally from central and southern Africa. The citron (*Citrullus lanatus* var. *citroides*) grows wild there, and is thought to be related to the wild ancestor of watermelon. The related species known as Egusi melon (*Citrullus colocynthis*) is found wild in west Africa and is also thought to be related to the wild ancestor of watermelon.

Watermelon is consumed for its fresh fruit, pickled rind, glacé candy, and for its dry seeds (harvested from confectionary type cultivars). The watermelon fruit contains 93 percent water, with small amounts of protein, fat, minerals, and vitamins (Table 1). In some arid regions, watermelon is used as a valuable source of water. The major nutritional components of the fruit are carbohydrates (6.4 g/100 g), vitamin A (590 IU), and lycopene (4,100

TABLE 1

μg/100g, range 2,300–7,200), an anticarcinogenic compound found in red flesh watermelon. Lycopene may help reduce the risk of certain cancers, such as prostate, pancreas, and stomach. The lycopene content of the new dark red watermelon cultivars is higher than in tomato, pink grapefruit, or guava. Orange flesh types do not contain lycopene, but have a high carotene (vitamin A) content. Citron and Egusi type watermelons are used to feed cattle in Africa. Watermelon seeds are rich in fat and protein.

Wild watermelons have hard, non-sweet, sometimes bitter, white flesh. Through plant breeding, the domesticated watermelon now being grown has fruit with a protective rind, sweet edible flesh, and bright red color. Specialty cultivars are available with orange, yellow, or white flesh.

Through history, watermelon was distributed throughout the world as trade and knowledge of central Africa developed. The crop was grown in India by at least 800 C.E., and in China by 1100 C.E. The Moorish conquerors of Spain introduced watermelon into Europe, where it was noted in Cordoba in 961 C.E. and Seville in 1158 C.E. Watermelon's spread into northern Europe was relatively slow, since it was not noted in the British Isles until late in the sixteenth century, perhaps because of the generally unfavorable climate for watermelon culture in much of Europe. About this time, watermelons were introduced into the New World, with culture of the plants noted in the Massachusetts colony in 1629. The introduction of watermelon into other parts of the world has followed established trade routes.

In the United States, Thomas Jefferson, as indicated in his garden record, was a watermelon gardener at Monticello, as was Henry David Thoreau in Concord, Massachusetts. Mark Twain wrote in *Puddn'head Wilson* that "The true southern watermelon is a boon apart and not to be mentioned with common things. It is chief of the world's luxuries, king by the grace of God over all the fruits of the earth. When one has tasted it, he knows what the angels eat." Even today, watermelon exerts an influence over popular culture in festivals throughout the rural South.

Watermelon is grown commercially in areas with long frost-free warm periods. Plants are widely spaced because of the long, trailing vines. They may be established in the field by planting seeds or by transplanting containerized plants. Management of plant pests (weeds, insects, and diseases, including nematodes) is essential during the production period. Three-fourths of the world production is grown in Asia (Table 2), with China the leading country in production.

Watermelons are grown in most states of the United States, but the major producers are in the South and West (Florida, Georgia, California, and Texas). The fruits are harvested by hand, with the most experienced workers doing the cutting (removal of the fruit from the vine) and

the others loading the bins or trucks. The fruits are shipped to markets throughout the country, with some exported to Canada.

Watermelon fruit will keep for two to three weeks after harvest if it is stored properly at 10 to 15°C and 90 percent RH. Besides whole watermelons, it is becoming popular to sell watermelon in pre-cut halves, quarters, slices, and chunks. Whole fruit are usually cut in the store under cold, aseptic conditions since the cut product does not ship or store well. Seedless watermelons are especially popular for pre-cut sales, since that shows their seedless quality.

In the 1800s, most watermelon was grown for local sales. Development in the last few decades of rapid shipping in refrigerated railroad cars and trucks has led to distribution of watermelon throughout the United States from major production areas. Southern production areas begin shipping early in the year, and the harvest continues throughout the summer in more northern areas.

Depending on the cultivar, watermelon fruit are produced in different sizes: ice box, small, medium, large, or giant; different shapes: round, oval, blocky, or elongate; different rind patterns: gray, narrow stripe, medium stripe, wide stripe, light solid, or dark solid; different flesh colors: white, yellow, orange, or red; and different types: seeded or seedless. Commercially, the most popular seeded cultivars are red flesh, blocky shape, and large sized (8–11 kg), like the cultivar Allsweet. For seedless watermelons, the popular cultivars are red flesh, oval shape, and medium sized (5–8 kg), like the cultivar Tri-X-313. Per capita consumption of watermelons in the United States is 7.2 kg (Table 3). Watermelon seeds can be harvested and roasted for eating as well.

Watermelon is served fresh as slices, as chunks (often in fruit salad), as juice, and as edible seeds for the confectionary types. In the United States, watermelon has typically been part of the summer picnic, where the

giant (15 kg) fruit is popular. Picnic events that feature watermelon include eating contests (who can eat the most), seed spitting (who can spit the seeds the farthest), or greased watermelon games (which team can move a greased watermelon—which floats but is hard to hold onto—over to its side of the lake). However, watermelon is no longer just a summer fruit and is becoming an everyday fruit like apples, bananas, and oranges.

**Cucumber (*Cucumis sativus*)**

The cucumber is thought to have originated in India, where it is found wild and is cultivated in many diverse

**WEST INDIAN GHERKIN (*CUCUMIS ANGURIA*)**

The West Indian gherkin (*Cucumis anguria* var. *anguria*), also known as the bur gherkin, was thought to have originated in the Caribbean, but now is considered to be of African origin. The African progenitor is *Cucumis anguria* var. *longaculeatus*, formerly called *Cucumis longipes*. It was probably brought to Brazil and the West Indies (where it got its name) by Africans in the slave trade. The term gherkin is also used for the pickling type of cucumber, especially the small sizes.

Fruit of the bur gherkin are smaller (5 cm) than those of the cucumber, but the defining characteristic of this species is the long peduncle or fruit stem (up to 20 cm in length). The fruit are light yellow to pale green, and are covered with short, fleshy spines. The fruit are eaten fresh or pickled.

forms. Accessions of *Cucumis sativus* L. var. *hardwickii* may be related to the original ancestors of the cucumber, and have been collected in the foothills of the Himalaya Mountains. These forms are not directly useable in agriculture because of their bitter fruit, dormant seeds, and late maturity. However, they have some traits that have been transferred to elite cultivars by plant breeders.

Secondary centers of diversity for the cucumber exist in China and the Near East. Related species are *Cucumis hystris* from China and the African *Cucumis*, such as melon (*Cucumis melo*), gherkin (*Cucumis anguria*), and their wild relatives.

Cucumbers were probably domesticated in Asia and then introduced into Europe, where the first cultivars were selected in the 1700s. The first cucumbers were brought to the Americas by Christopher Columbus, and Native Americans were growing cucumbers from Florida to Canada by the early 1500s. Formal plant breeding began in the United States in the 1880s, when cultivars diverged into fresh-market (slicing) and processing (pickling) types.

The cucumber is grown for its fruits, which are eaten fresh or pickled in most countries, but which are also eaten fried (usually when fruit have been harvested at a more mature stage). Slicing and pickling cucumber fruit are mostly water, but they provide some vitamin A and C, especially when pickled with dill and other spices (Table 1). Cucumber is the ideal food for people having trouble with body weight, because it is mostly water, with some fiber, and few calories. Cucumber causes burping and mild stomach upset in some people when eaten raw, but not when soaked in vinegar or pickled before eating. Cucumber is also among 35 fruits, vegetables, and herbs identified by the National Cancer Institute as having cancer-protective properties.

Cucumbers are served and eaten at home and in restaurants (especially fast food establishments) where pickle chips or relish are served on hamburgers and hot dogs. Pickles are also served as appetizers. Fresh cucumbers are sliced and served in salads or as garnishes to add color to the meal. Per capita annual consumption of fresh cucumber is 3.1 kg and processed cucumber 2.2 kg in the United States (Table 3).

Cucumber is used in most countries in the world, where particular types have been developed to fit local requirements. The common types are American pickling, American slicing, European greenhouse, Middle Eastern (Beit Alpha), Dutch pickling (parthenocarpic), oriental trellis, and specialty (such as the round or "lemon" cucumber). Some types referred to as cucumber, such as Armenian cucumber, are actually melon (*Cucumis melo*).

Fresh-market cucumbers are grown primarily in the southern and western states of the United States, especially Florida, Georgia, North Carolina, Texas, and California. Processing cucumbers are grown from Mexico to Canada so they are available year around for processors,

often at a considerable distance from the production site. About 80 percent of the world's cucumber production is in Asia (Table 2), with China being the leading producer (Table 4).

Cucumbers are harvested by hand for fresh-market use, and by hand or machine for processing use. Michigan and Wisconsin have an estimated 50 to 75 percent and 25 to 50 percent machine harvest, respectively. Once-over harvest machines destroy the vines as they harvest the fruit (pickling type only). After harvest, the fruit are cooled, graded, packed, and shipped. The cucumbers will have fewer post-harvest rots and a longer storage life if they are cooled soon after harvest.

Fresh-market cucumbers are transported to market and displayed for a few days for sale to consumers. The fruit may be shrink wrapped in polyethylene or coated with vegetable wax to extend shelf life, or they may be sold with no protection. For fresh-market cucumbers, storage at 50°F (10°C) and 95 percent relative humidity (RH) will permit the produce to hold for approximately two weeks after harvest. The American slicing type cucumber has a thick tough skin to reduce shipping damage and increase storage life. Pickling cucumbers are graded and then loaded into tanks of brine (salt water) for fermentation and storage.

The pickling industry originally used brine tank storage to provide brine stock (pickles) to the factory during the off-season. Currently, however, more than half of the crop is processed without brining. Pasteurization is used to produce fresh pack pickles, and refrigeration is used to produce overnight pickles. Fermentation in brine tanks is used less for storage now, and more to produce particular types and flavors (for example, by using acetic acid or lactic acid fermentation).

Storage of pickling cucumber is usually in barrels, pails, jars, or plastic pouches. Preservation is by fermentation, pasteurizing, or refrigeration. For pickling cucumber, it is common and economical for growers to supply markets around the world. For example, growers in India and Sri Lanka supply small pickles in barrels of vinegar or salt brine to processors in Europe and North America.

In the 1700s, cucumber production in the United States probably was small scale; individuals and families would grow a few plants in their garden for the home, probably using the fruit fresh during the summer harvest season and pickled (using a favorite recipe to preserve the fruit) during the off-season. In the 1800s, family farmers grew small areas of cucumbers to supply the fresh market and pickle companies. Even when growers became specialized in cucumber production in the 1900s, family farmers continued to supply small size (grade 1, under 26 mm diameter) fruit to pickle companies. Large field crews generally do not harvest each field every day and usually do not search the vines for small fruit as required to produce a high percentage of grade 1 fruit from the field.

Cucumber production is now being done by growers with large farms, specialized equipment, and excellent marketing skills. The small-scale production of cucumber has also increased, as home gardening in the United States has become very popular.

The major modification made to the cucumber in the 1930s was to begin breeding for disease resistance. In the 1960s, gynoecious cucumbers (pistillate or female flowers at every node) were developed, and are now used to make gynoecious hybrids using bee pollination (rather than the more expensive hand pollination). The gynoecious hybrid cucumber, usually with 15 percent monoecious hybrid pollenizer seeds blended into the seed packet, is a major success story. Current cultivars are resistant to anthracnose, downy mildew, powdery mildew, angular leafspot, scab, fusarium wilt, cucumber mosaic virus, and other major diseases found throughout the United States.

Plant breeders have developed a new type of cucumber capable of being grown in the greenhouse. The modifications include making the plant gynoecious (all pistillate or female flowers) and parthenocarpic (fruit set without pollination to eliminate the need for bees or hand pollination, and making the fruit seedless), and of high quality (genetically bitter-free plant for mild-flavored fruit).

Other modifications made by plant breeders include the development of cultivars having large diameter fruit for use in chipping. Thus, a sandwich or hamburger can be made using one large-diameter pickle chip rather than three of the standard size. However, that development was negated by the use of large pickling cucumbers (grade 3) sliced longitudinally to make a rectangular chip. Two of those can be used on a sandwich or hamburger instead of the single large chip, and the quality is often superior.

**Melon (*Cucumis melo*)**

Melon originated in southern Africa and has many wild relatives there. Related species include cucumber (*Cucumis sativus*), the West Indian gherkin (*Cucumis anguria*), and the

A cucumber melon in the Kalahari Desert of southern Africa. This region is also the genetic homeland of the watermelon. © ANTHONY BANNISTER: GALLO IMAGES/CORBIS.

horned cucumber (*Cucumis metuliferus*). Cucurbits, including melons, have complex symbolic associations with sex and sexuality, fertility, abundance, and gluttony. They may denote wealth in areas where melons do not normally grow.

Melon fruit have a high water content (about 90 percent), and contain sugars and fiber. Nutrients found in melon include vitamin C, and in the case of muskmelon (and other orange-fleshed types), carotenes. Nutritional compositions of casaba, honeydew, and muskmelon (cantaloupe) are shown in Table 1.

The major changes made by plant breeders to the domesticated melon compared with wild relatives have been to add disease resistance, remove seed dormancy, increase fruit size, increase the size of the mesocarp (the edible portion of the fruit), improve the quality, reduce the frequency of defects, and increase the sugar content.

Melon was brought from Africa to Europe and Asia, and from Europe to the Americas. It is now cultivated throughout the world, where specific types have been bred for local use. A useful horticultural classification of melons follows:

- The *Cantalupensis* group includes cantaloupe, muskmelon, and Persian melon. The fruits are oval or round; sutured or smooth; mostly netted, some slightly netted or nonnetted; and abscise from the peduncle when mature. The flesh is aromatic and is usually salmon or orange in color, but may be green. In the United States, the term “muskmelon” and “cantaloupe” are used interchangeably, but some horticultural scientists suggest that they be used to distinguish between types of the *C. melo Cantalupensis* group. This group includes the *Reticulatus* group used in some older classifications.
- The *Inodorus* group includes winter melon, casaba, Crenshaw, honeydew, Juan Canary, and Santa Claus. The fruits are round or irregular, smooth or wrin-

kled, but not netted; nor do they abscise from the peduncle at maturity. The flesh is mostly green or white, occasionally orange, and not aromatic.

- The *Flexuosus* group includes the snake or serpent melon and the Armenian cucumber. The fruits are quite long, thin, ribbed, and often curled irregularly.
- The *Conomon* group includes the oriental pickling melon. The fruits are smooth, cylindrical, and may be green, white, or striped. The flesh is white and can taste either sweet or bland.
- The *Dudaim* group includes mango melon, pomegranate melon, and Queen Anne’s melon. The fruits are small, round to oval, and light green, yellow, or striped. The flesh is firm and yellowish-white in color.
- The *Momordica* group includes the phoot and snap melon. The fruits are oval or cylindrical with smooth skin that cracks as the fruit matures.

Melons require a long growing season with warm, sunny days and cool nights to achieve maximum quality. Plants are established by seeds or containerized plants after danger of frost is past. Stringent management of plant pests is necessary for high yield and quality. As with other cucurbits, it is necessary to have a large honeybee population to facilitate pollination. Asia produces about two-thirds of the world supply, with China being the largest producer (Tables 2 and 4). Several countries in Central America are major melon producers for export to the United States in late winter and early spring. In the United States, most melons are produced in California, Arizona, Texas, and Georgia. In Japan, melons are grown in greenhouses to produce high quality fruit commonly used as gifts.

Melons are harvested by hand from the vine. Maturity in the *Cantalupensis* group is by separation of the fruit from the peduncle (fruit stem) with minimal force. Maturity in the *Inodorus* group melons is not as easily determined, and they may be treated with ethylene after harvest to enhance the ripening process during transit to the market. Cantaloupes are best stored at 3°C and 95 percent RH, whereas other melons are best stored at 7°C and 95 percent RH. The effective postharvest life is about two weeks for both types.

Melon is served fresh as slices, chunks, or juice. Chunks are often used in fruit salad, made into melon balls and frozen, or prepared and sold in grocery stores to be eaten as is. Total per capita melon consumption in the United States is about 7 kg (Table 3). The vitamin A and C content make melon a nutritious food (Table 1).

**CUISINE, EVOLUTION OF.** Throughout evolutionary history humans have prepared or transformed foods to make them edible. The preparation of food before consumption, which is the foundation of cuisine, has always been a part of the human behavioral repertoire and helps define the species. Unlike most related mammals and primates that begin their digestion in the process of chewing their food, humans often begin digestive processes outside of the body, using tools for this purpose. In other words, what humans do to food before eating it often transforms the food in ways that make it more digestible.

Abundant archeological evidence shows all kinds of tools used for food preparation throughout human evolutionary history. For example, ancestors from the genus *Homo* perfected tools that could cut a piece of meat more effectively than their canine and incisor teeth. They found they could crush a nut or other hard seed pod more efficiently with a stone pestle than with their molar teeth. Human ancestors added controlled use of fire several hundred thousand years ago, so apparently the potential for predigesting food outside the body was well developed by the time *Homo sapiens* emerged. From a biological evolutionary perspective, the continued use of tools and fire and the broad effects of the domestication of plants and animals has altered important aspects of the human food chain and has significantly affected the evolutionary dynamics that underlie the species.

The effect of these important developments in the processing of foods is most evident in human digestive tracts and some of the metabolic pathways associated with the foods humans eat. Evolutionary biologists refer to the changes in the human digestive tract as a result of a relaxation in evolutionary selection. This is evident in the variability of structures that no longer have importance for survival, such as in the structural reduction in size and formation of human teeth or the function of the appendix.

Much of this biological evolution occurred prior to the origin of agriculture that was marked by the domestication of plants and animals. The enormous success of

agriculture and horticulture (beginning approximately ten thousand and five thousand years ago respectively), provided the practicing societies with the ability to feed an excess number of their members and thus served as the basic economic subsistence engine for the broad emergence of human civilizations and the overall growth of humanity to its megapopulation size.

### Influences of Agriculture

Since the Neolithic era, agricultural practices have continuously improved the productivity of certain plants over others. This intensification has led to an increased dependence on fewer and fewer plants to provide the bulk of most human diets. However, no single plant or any small group of plants, when consumed as raw products from the field, can satisfy all of the nutrient needs of the species. Hence, dependence on fewer plants could have produced nutritional problems (and to some extent this did happen) if humans had continued to eat them more or less raw, as more ancient ancestors did over the thousands of years before the Neolithic era. Thus the Neolithic agricultural diet, characterized by a narrow range of cereal grains and legumes, represented a substantial change from the Paleolithic diet, characterized by a great diversity of hunted and gathered foods. However, this substantial change in diet raises important questions about how and if the species continues to evolve biologically in response to the decrease in the diversity and contents of diets brought about by agriculture.

The relatively rapid shift to an agricultural diet represented a significant nutritional challenge because the diets were largely dependent on relatively few cereal grains and legumes that had serious nutritional limitations. These new limitations included specific nutrient deficiencies, antinutritional properties (such as anti-trypsin factors, high levels of phytates, and lectins), and various toxic constituents (such as cyanates and tannins). This shift to agriculture could and did result in strong new sources of natural selection and the rapid evolution of biological traits that tended to compensate for these limitations. However, the vast majority of the adaptations to this new agriculturally based diet came from the increased use of cuisine-based technologies that went far beyond the use of tools and fire, already well established in Paleolithic times. In essence the emergence of a wide variety of cuisine technologies counterbalanced the more limited but important potential of the genetic changes required to adjust to the nature and rate of these new dietary constituents.

It is clear that significant biological adaptations underlie the success of the evolution of some agricultural practices. Many experts accept the evidence that it is the continued secretion of lactase enzyme that makes milk sugars digestible by most northern European adults in contrast to most other adults of the world, who stop secreting the enzyme at the time of weaning. This evolved trait for adult lactase enzyme sufficiency underlies the

high and continued dependence of these populations upon dairy foods following the domestication of cattle over eight thousand years ago. Although the specific cultures of northern Europe have undergone many cultural and historic changes in diet over that long period, all of those cultures continue to consume dairy foods in unbroken traditions, such as making yogurts and cheeses that partly lower the milk sugar content. Likewise, good evidence indicates a genetic cline (or gradual geographical change in the gene frequency) of adaptations to the gluten protein in wheat (to which some people have serious intolerance) tracked with increasing frequencies from the Levant, where wheat was first domesticated, all the way across Europe, where it was introduced at later times.

Other genetic adaptations involving nutrition and food also work pharmacologically to influence disease problems. For example, the disease called favism, which results in a profound life-threatening, hemolytic anemia, is due to another enzyme deficiency that helps protect the affected populations from malarial infection. However, the gene Glucose-6 dehydrogenase deficiency (G6PD), a sex-linked gene associated with males, makes afflicted males particularly sensitive to the profound hemolytic effects of the oxidant compounds in the beans. Although the G6PD gene is widespread in all of the regions where fava beans are consumed and causes many deaths every year among sensitive individuals, the pharmacological effects of the beans help prevent malaria. Not surprisingly, more myths and stories promote and prohibit the consumption of these beans than any other food in Indo-European history. Thus foods may have pharmacological properties in addition to nutritional properties, which makes interaction between their consumption and the continued evolution of the populations that eat them complicated.

While genetic adaptations to diet did evolve over the last ten thousand years, most adaptations to agricultural diets evolved at the cultural realm in the form of cuisine technologies. While becoming more dependent on fewer plants in the diet, human forebears produced a classic evolutionary bottleneck in which the increased dependence on fewer plant crops increased the nutritional liabilities each plant retained. Consequently, a continuous complementary evolutionary process related the increased agricultural productivity with the evolution of new cuisine technologies that enhanced the nutrient composition and often simultaneously rid the plants of their toxic and antinutritional effects.

### Nutriculture

The term “nutriculture” refers to the reciprocity of these preparatory technologies with the overall advantages that agricultural practices have provided for the enormous success in increasing the productivity of plants. In other words, every advance in the agricultural productivity of plants was accompanied by the evolution of cultural strategies to offset the nutritional disadvantages of de-

pending on so few nutritionally unbalanced and potentially toxic foods. Hence “nutriculture” represents the evolved cultural strategies that turn these disadvantages into advantages and the complementarity of these preparative technologies with agriculture. Treating foods before they are consumed can and often does have nutritional and pharmacological consequences for the finished consumable. For example, many different physical, chemical, biochemical, and microbiotic steps “prepare” the plant-based staples in the human diet. These transformations from the “raw to the cooked” become the culturally recognized foods humans eat, and with which they celebrate, remain nutritionally healthy, and ultimately survive and prosper around the world. Thus the evolution of food nutriculture has been just as important as the success of agriculture in producing enough food to continue to feed the world.

In fact many of these technologies become parts of long-standing recipes that fill this encyclopedia and the cookbooks and cooking traditions of the world. These technologies are so important in defining the foods consumed that they become part of the cultural worldview of every society that has ever lived. Every society celebrates with food and incorporates foods as symbols, and many of these traditions provide the cultural memory for how foods should be prepared for healthful consumption.

Although evolutionary anthropologists and biologists have not looked at what humans do to food as part of an evolutionary process equal in importance to agricultural practices, the evidence for such a process underlying basic cuisine practice is strong. Of course this does not mean that every aspect of cuisine practice involving innovations, presentation, and the like has some kind of evolutionary basis. However, it does suggest that many of the fundamental aspects of the transformation of raw materials into foods often has a long and highly evolved natural history that is not always readily recognized as optimizing their nutrient and other qualities. Hence transforming the raw foods for consumption can and does make a difference in health and survival. In some respects this knowledge about preparation and consumption of foods is so much a part of the existence and identity of a society that its members often are more conscious of making food “palatable” to culturally conditioned tastes and expectations than of the nutritional and pharmacological significance of the steps taken.

### Importance of Preparation

Other major sources of nutrition follow the nutricultural principle. A classic example of the evolution of cuisine practices involves maize or “corn.” While maize is the most productive crop in the world, and virtually all of the great Mesoamerican civilizations depended upon it as a staple, it is not nutritionally the best balanced of staples. Maize has low lysine and tryptophan levels, and its niacin levels, when stored as a staple, are nutritionally indigestible. Specifically the B vitamin niacin becomes bound

in a complex called niacytin, and this bound form is indigestible to the effects of stomach acid and gastrointestinal enzymes. However, it is known that the chemical bond that makes niacytin resistant to digestive acid is broken in the presence of an alkali that frees the bound niacin. Although humans can make a small amount of niacin from the essential amino acid tryptophan, corn is deficient in tryptophan. Fortunately beans have relatively high levels of tryptophan, and as long as beans are consumed with corn (maize), the diet is balanced. However, if beans and other regular sources of tryptophan or niacin are not available in the diet, the disease pellagra makes people sick with diarrhea, dermatitis, dementia, and ultimately result in death.

While alkali treatment also enhances the solubility of lysine, it is not universally used, even in the Americas where the crop evolved. However, the Native American societies that were high consumers and growers of maize always used alkali in their cuisine technology. It was a one-to-one relationship between high consumers and growers and their subsequent use of this critical step in the preparation of their food staple. In terms of their recipes, the added alkali was prepared in several different ways, including crushed limestone, roasted mollusk shells, and wood ashes. The net effect of this step was always the same. The food was heated and “cooked” in the lime, and then most of the alkali was removed prior to consumption. Even though the recipes varied among different cultures and traditions, these basic cooking steps did not vary.

In this regard it is interesting to note that Christopher Columbus, who first introduced maize to the Old World, only introduced the food and not the critically important recipe. Pellagra became widespread, resulting in a gradual decrease in the use of maize as a human food. Not until the discovery of vitamins beginning in the 1920s, over four hundred years later, was pellagra defined as a nutritional deficiency associated with the consumption of maize.

However, considering the history of every major civilization, it becomes clear that all depended upon the solutions to similar problems to survive and prosper. Thus, while it is possible to innovate new food technologies that may not have many or any negative consequences in times of nutritional abundance, the same practices may produce serious deficiencies during times of nutritional stress. Thus food preparation has substantial survival advantages, and undoubtedly significant wisdom resides in the related food practices that maintain food preparation traditions.

The use of fermentation to enhance the nutrients of wheat and barley in the production of beer and bread is a classic example of how foods become staples of the diet. Fermentation of wheat and barley with yeast not only produces the alcohol in beer and, to a lesser extent, in bread; it also synthesizes nutritionally essential amino acids from nonessential ones, reduces the toxicity of the

tannins in the wheat, and lowers the phytate levels that interfere with calcium absorption. Squeezing, crushing, and heating the manioc (a good source of nutrition known throughout the world for yielding the tapioca starch of dessert puddings) reduces the plant’s cyanide content, which can be so high that even breathing the cooking fumes can be deadly. With the notable and important exception of fruits, which evolved to attract mammals to eat the seeds and thus to disperse them, the raw produce is not a viable source of nutrients without the culturally evolved capacity for transforming it into an appropriately edible food.

## Biology and Culture

Over time, a trial-and-error process results in the nutritive success or failure of new cuisine strategies. Those strategies that satisfy basic nutritional needs become incorporated into food traditions and provide subtle and not so subtle advantages to the people who practice them. When the cause-and-effect relationship between the cuisine practice and the outcome are readily evident, as in changing the appearance, taste, or aroma of a food and then noting a benefit, it is relatively simple to understand the functional significance of the cuisine practice. However, when considering subtle cause-and-effect relationships not readily evident and expressed some time long after the prepared food is consumed, it is difficult to detect the relationship and consciously to behave in the appropriate way. For example, the time it takes to develop a nutritional disorder for a vitamin like niacin is so long that the appropriate cuisine practice may not ever evolve, as was the case for extracting the niacin from maize in Europe. Epidemiological studies of long-term disease outcomes that may extend over a substantial portion of a lifetime, such as cardiovascular disease and some forms of cancer, demonstrate how subtle some of these effects are.

On the face of it, the degree to which a culturally based diet satisfies basic nutritional needs is a matter related to the biology of humans as omnivores. Humans uniquely depend on cultural adaptations concerning diet to solve the nutrient problems that biology is incapable of solving on its own. Instead, humans have discovered and encoded in cultural traditions wisdom about diet that provides a culinary prescription for survival and good health. What people eat is largely dictated by cultural traditions, but the degree to which a diet satisfies basic nutritional needs largely depends on human biology. This obvious interface between biology and culture has encouraged the development of a new approach or paradigm that analyzes and interprets biological and cultural adaptability as continuously interacting phenomena throughout human evolution.

No doubt the evolution of agriculture would not have occurred without these counterbalancing nutricultural evolutionary steps. In fact this basic theme of nutriculture is repeated with other aspects of cuisine and thus forms

the basis of a broad trend throughout history in the consumption of every major plant food.

The remarkable growth of knowledge about what people eat arises from an understanding of both the pre-history of diets and the recorded history of foods. Also a substantial and growing ethnographic and cross-cultural literature concerning folk cooking practices allows tests of specific hypotheses about food processing. The available data in food science and technology, the nutritional sciences, biochemistry, ethnobotany, pharmacology, and the neurosciences is extensive. Using this knowledge to extend the understanding of the biological and biocultural evolutionary processes produces the potential for providing important insights about this nascent study of nutriceulture. The varied contents of this *Encyclopedia of Food and Culture* suggest avenues and examples of nutriceulture for exploration.

**CURDS.** Curds are a by-product of milk, and in the traditional agrarian societies of Europe and America, indeed in most parts of the world, the processing of milk belonged to the woman's sphere. In many farmhouses, there was a cold room or a freestanding springhouse nearby known as the dairy, and like the kitchen, this was the domain of the wife and her daughters. For this reason, much information about curds and curd-making can be found in cookery books and in books on household management.

Curds may be best described as condensed milk fat that has not yet aged into cheese, although it is also fairly common to refer to unpressed curds as "fresh" cheese—fresh in the sense of raw or unprocessed. The most popular form of curds consumed in the United States is cottage cheese, which is fresh curds combined with cream, sour cream, or milk. Low-fat cottage cheese is generally considered a health food and therefore plays an important role in many types of weight-loss diets. Greek feta cheese is essentially fresh salted curds preserved in whey, the watery liquid that comes with every jar or package of feta.

The word "curd" evolved from Middle English *crowden*, a verb meaning 'to press or push hard in a downward direction'. This association may derive from the fact that curds were normally poured into a cloth bag and pressed dry of the whey, or hung from a hook and allowed to drip over a basin, hence the old term "hung cheese." In the eighteenth and nineteenth centuries,

#### GOAT CURDS

Goats lactate seasonally and while they produce less milk than cows, their milk is richer in vitamins and minerals. The ancient Greeks always recommended goat milk for babies because they observed that it was easier to digest. This is due to the fact that a high proportion of small- and medium-chain fatty acids are more easily absorbed into the body. Likewise, goat curds are much easier to digest than curds from cow milk. Goat milk is naturally homogenized because it lacks a protein called agglutinin; thus the fats in the milk remain dispersed. This, plus the lower casein proteins in goat milk, results in smaller curds, which is why fresh goat cheese has such a dense paste-like texture. The halloumi cheese of Cyprus is so dense that it can be grilled without melting or falling apart. It is made from goat curds that are pressed together with mint, then heated in salted whey.

curds were also pressed into molds made of ceramic or tin and sold in farm markets in a wide variety of shapes, usually hearts of various sizes.

From *crowden* also comes the Southern term “crowder,” any sort of cowpea that was cracked (pounded) and cooked for porridge. A crowder pea was a porridge pea, and in the Scotch-Irish cookery of Appalachia, this porridge might also contain whey or curds, or even both. In rural Scotland, curdy-butter or cruddy-butter was a spread for oat cake made by mashing together fresh curds and salted butter. In Appalachia, it was eaten on johnny cake. It goes without saying that curds and whey have been dietary staples for thousands of years in every household where milk was readily available.

In composition, curds are the fatty part of milk that has become solid. When milk undergoes acidification, it sours. This souring process is induced by lactic acid bacteria streptococci and lactobacilli. They feed on milk sugars (lactose) and change it to acid. When this happens slowly at room temperature, the result is clabber or “thick milk,” as it was often called in Colonial America. Clabber is milk that has attained a consistency resembling junket, and in this form, it was an important ingredient in traditional cookery. It was also eaten by itself as a breakfast and supper food, often mixed with fresh fruit (during the summer). German *Quark* is very similar to clabber in composition and is eaten like yogurt in many parts of Central Europe. Clabber is no longer eaten in the United States because of regulations requiring the pasteurization of milk. Pasteurized milk will not clabber because the bacteria have been killed during the heating process.

However, when the souring process of raw milk is speeded up, the acid causes the fatty solids in milk to migrate and stick together, thus forming curds (called protein clump among cheesemakers) and watery whey. In traditional cookery, whey was considered a useful food in its own right, mainly because it was easy to digest. It was therefore employed in foods prepared for children, the elderly, or the sick. In regions where dairy culture predominated, whey was available in such abundance that it was often fed to livestock, especially pigs. Whey was also used in hearth cookery for making griddle cakes, muffins, and cornbread, since the acid would react with such old-time leavening agents as Hirschhorn salts, saleratus, and pearlash. Cow’s milk yields the largest amount of whey since it is about 85 percent water.

### Renneting

Curd formation could also be hastened by a process known as renneting. This was based on an enzyme called rennin, which is found in the stomach lining of ruminant animals. The rennet preferred by most cheesemakers generally came from the stomach of a young animal, such as a calf for cow’s cheese, kid for goat cheese, or lamb for sheep’s cheese. The use of animal rennets in cheesemaking is the reason many vegetarians will not eat

Traditional tin curd molds. Left top and bottom: Pennsylvania, circa 1900; right: France, circa 1890. ROUGHWOOD COLLECTION. PHOTO CHEW & COMPANY.

cheese—the young animal of course must be killed in order to obtain the rennet. Tofu, a curd made from soybeans, has been eaten in Asia as a milk curd substitute for over a thousand years. However, there is also a long history of rennets obtained from plants, and cheeses made with them are acceptable to those vegetarians who consume dairy products.

One of the earliest known plants employed as a renneting agent was the wild artichoke of the eastern Mediterranean and North Africa. It is believed that the Phoenicians discovered this process and disseminated the technology, since the earliest cultivation of artichokes (and cardoons) is associated with Phoenician colonies. These plants may have been first brought under cultivation expressly for their renneting qualities, only later employed in cookery. In any case, it was the “choke” or flower head that was heated in the milk in order to make it curdle. These plants flower in late spring when milk production is at its peak, especially among goats.

Other renneting plants from this same region were milk thistle (*Silybum marianum*) and blessed thistle (*Cnicus benedictus*), which were also eaten as spring greens (the leaves were tied up and blanched under mounds of soil). In northern Europe, the flower heads of several species of native thistles were used in the same manner, as well as the old Celtic rennet plant, Lady’s Bedstraw (*Galium verum*). In the case of Lady’s Bedstraw, it is the golden yellow root that is used to curdle milk. In the Celtic areas of Spain and Gaul, this plant, like milk thistle and blessed thistle, was under the protection of the fertility goddess Brigantia, who presided over matters dealing

with the dairy and whose name survives in many place names where her cult was celebrated annually at Imbolc (February 1).

Brigantia's offices were subsumed by the early Church and assigned, in Ireland at least, to St. Bridget (a goddess transformed into a saint) as well as to Maria Lactans, the Virgin Mary depicted with streams of milk flowing from her breasts. It was Maria Lactans to whom village women prayed not only to ensure their own lactation after childbirth, but also to ensure the proper curdling of milk during cheesemaking.

**CURRY.** The term "curry" is an Anglicized spelling of Tamil *kari*, a general term for any spiced sauce, or in some south Indian dialects, an old word for black pepper. There is no fixed recipe for curry, and the Indians themselves generally refer to this broad range of spice preparations as *masala*, such as the powdered *garam masala* of the north, *chat masala* (tart and salty), *kala masala* (black curry), and *dhansak masala* (hot Parsi curry). These can be blends of powdered or whole spices and seasonings, wet or dry mixtures, mild or hot, depending on preference and regional style of cooking. As a rule, northern Indians favor dry powders, while in the South, pastes are more common. Most Indians prefer to make

their spice mixtures fresh from raw or green ingredients, and this is one reason why recipes prepared in India taste so differently when made abroad.

However, curry, not *masala*, is now used the world over as a symbol for the spicy food of India, and especially for flavorings made for export, with powders based on such key ingredients as ground mustard seed, turmeric, coriander, cumin, and fenugreek. Cinnamon, cardamom, and chili peppers may also be added, as well as a variety of other flavorings. Most commercial curry powders are yellow, due to turmeric, a spice often connected with magic and ritual in traditional India. In spite of their universal appeal, spicy foods were condemned by most of India's ancient religions and forbidden to those seeking an austere and virtuous life. Curried foods were, therefore, equated with luxurious living.

Judging from the poems extolling them, the concept of serving a spicy sauce over rice is extremely old in India—there are references to crab and vegetable curries from ancient Jaffna in the south, but the term "curry" was not used to describe them. The Portuguese may have been the first Europeans to mention this type of cookery as early as 1502, but it was the Greek and Roman traders who first encountered it many centuries earlier. The traders are mentioned in Tamil accounts, which make it clear that they were quite fond of south Indian cookery, at least along the coast where they had established trading ports. The use of spice mixtures to flavor sauces, however, was not strange to either the Greeks or Romans, and such common curry herbs as cumin and fenugreek were actually introduced to India from the Mediterranean at a very early date.

The earliest reference to curry in English appeared in a 1598 Dutch travel account, but it was English cookbook author Hannah Glasse who first published a curry recipe in 1747, transforming it from a true sauce to a stew. This began the gradual yet steady evolution of curry into a dish quite at odds with its original Indian forms. Both the Dutch and English, through East India trade, spread the popularity of curry far beyond its original borders, but in doing so, they also changed it. The Dutch created the *rijstafel* and its numerous curried dishes out of their culinary experience in Indonesia. The English did the same with Indian *masala*.

True Indian-style curried sauce and rice are mentioned in numerous English accounts of life in India, even during the eighteenth century, and this remained a feature of the typical colonial meal; yet when it traveled back to England, it changed into a meat stew with rice added, or into something else altogether—such as the main flavoring for mulligatawny soup. Eliza Acton listed several curry dishes in her *Modern Cookery* (1847), including a rather telling discussion of curry, along with potted meats—telling because of its positioning among hashes as a supper dish or something for high tea, not a main course. She not only supplied a recipe for curry very sim-

ilar to the powdered sorts sold in tins during that period, but she also detailed directions for making curried eggs (deviled eggs flavored with curry), curried sweetbreads, and curried oysters.

American cookery books do not trace as avid a taste for curries as their English counterparts, but Eliza Leslie did tackle curry in her *New Cook Book* (1857), and complained about the common adulterations and the widespread overuse of turmeric and hot chili. She made an interesting remark: "The best curry powder imported from India is of a dark green color, and not yellow or red. It has among its ingredients, tamarinds, not preserved, as we always get them—but raw in the shell. These tamarinds impart a pleasant acid to the mixture. For want of them, use lemon." Leslie was describing a true *masala*, and she stands out for taking a stance on authenticity mostly lacking in European cookery books of her period. However, her words were to no avail.

Tinned curry powder, imported or imitation, became a standard household spice, because it was an ideal ingredient for dressing up processed foods and the sort of bland preparations championed by the home economics movement of the late nineteenth and early twentieth centuries. Suddenly, curry was everywhere, "Beetonized" by the publishers of Isabella Beeton's *Book of Household Management*, the culinary bible of the British Empire. Curry met its ultimate apotheosis in the empress of India, the aging Victoria, presided over by Indian manservants and an Indian groom.

On the commercial side, marketing genius E. P. Veerasawmy promoted this lifestyle of the imperial raj as Edwardian chic. His food specialty company (established 1896) and famous restaurant on Regent Street in London (established 1926) became English institutions and synonymous with the "other English cuisine." Veerasawmy was also a champion of authenticity in his culinary writings. In *Indian Cookery* (1957), he said about curry: "Curries should always be served in separate dishes and never with rice as a border. The accompaniments of rice with curry are usually Bombay ducks, puppadums, chutneys (various kinds), Indian pickles, and sambals. It is best to eat curry and rice with a dessert spoon and fork. A knife should never be used. A well-cooked curry will not need one."

If curry has undergone a change since then, it has taken its cue from the large numbers of Indians and Pakistanis who have settled in Britain, Africa, South America, and the United States during the second half of the twentieth century. No longer do non-Indians imagine that curry is a flavor peculiar to one rare fragrant spice. The proliferation of Indian-style restaurants, especially the inexpensive ones with highly varied menus, has at least driven home the idea that curried sauces come in many styles and forms. Most importantly, however, is the printed menu itself. All over the world, anywhere English is spoken, Indians prefer to use the term curry, regardless of what they may call their sauces in the homeland.

**CUSTARD AND PUDDINGS.** Custard and puddings are words that describe several important sweet foods. The strict culinary definition of custard is eggs and milk mixed and baked, or stirred over gentle heat until thickened. Used in desserts, pies, pastries, and as sauces, it is well known in European countries and in cultures influenced by them.

After this, there are significant differences between custards and puddings in North America and the United Kingdom. Currently, in North America, pudding, and often egg custard, is made up from a flavored cornstarch mix to give creamy-textured desserts, and is eaten alone or used as pie filling. Mixes are also known elsewhere, for instance, in Germany, Central Europe, and Southeast Asia. In Britain, pudding mix is unknown, but a similar product, custard powder, is found in most kitchens. It is vanilla flavored and used mostly to make a sauce for puddings. Puddings are a complex subject in English cookery. The word "pudding" is used for numerous sweet dishes—some crisp, some cake-like, some soft and smooth, some like plum pudding. They have no convenient overall definition, but sweetness and the presence of flour or other cereal is important, and they are essential to a proper dinner. Pudding is also used as a collective name for the dessert itself, and applied to special groups of savory foods, not discussed here.

In scientific terms, cornstarch puddings are starch gels, and egg-and-milk custards are protein gels. To achieve their creamy texture, old-fashioned cornstarch pudding mixes and British custard powder must be brought to the boil. This gelatinizes the starch: the granules of which it is composed swell and some long-chain starch molecules migrate out, making the liquid thick and viscous. When this cools, it becomes gel in which the starch molecules form a network, enmeshing the water. Instant pudding mixtures rely on chemically modified starches that

## CUSTARD PIES

The appearance of early custards is unknown. In seventeenth-century England, the author Robert May (1685) gave patterns for baked custard tarts. Pastry for the base was cut to make fancy leaflike shapes. Vertical strips were added to the edges to make walls to retain the mixture. The shapes were baked blind, then filled with flavored egg and milk, and baked again to set the custard, which was finally decorated with a sprinkle of little colored candies. These custards were probably eaten by spooning the filling out of the pastry, which recipes suggest was tough and essentially for structural and decorative purposes.

Such elaborate dishes are unknown today, and custard pies are plain in appearance, their only decoration being a scatter of grated nutmeg, but individual custard tarts are made in deep pastry shells, recalling a little “flowerpot” shape, originally known as a *dariole*. The large French apricot tarts with custard baked around the fruit are not found in English cookery. A short pastry is always used for the crust in England, unlike Portuguese *pasteis de nata*, rich custard tartlets in flaky pastry.

Several distinctive North American variants of custard pie have appeared. These would not necessarily be considered custard pies by their makers, but a certain basic reliance on eggs and milk can be seen in the recipes. They include pumpkin pie, key lime pie, chess pies as made in the southern States, lemon meringue, and various “cream” pies. These products represent a distillation of centuries of ideas about custard and puddings from various European cultures, with some distinctively American twists added. Finally, custard pies also became important in early movies, but as ammunition, rather than as food. They were specially constructed with pastry sturdy enough to hold in the hand and included a satisfyingly messy filling.

gelatinize without heating. Flavors of pudding mixes are limited only by technology and the tastes of consumers; almond, vanilla, chocolate, coconut, caramel, butterscotch, and lemon are considered old favorites.

Egg-based custards require gentle cooking. A standard recipe is one cup milk, scalded, mixed with two eggs and two tablespoons sugar, poured into a dish or a pie shell and baked at an oven temperature of about 350°F (180°C). During baking, the egg proteins coagulate to become a firm but tender gel (milk contains naturally occurring salts that aid this process). Alternatively, the mixture is cooked in a double boiler on the stove top to make

a boiled custard. This is a confusing name, as the temperature of the custard must not rise above 189–193°F (87–90°C) or it curdles and the texture is spoiled. Richer custards require cream or high proportions of egg yolk.

Custard or pudding recipes that involve both cornstarch (or flour) and eggs are also known; *crème pâtissière* (pastry cream) is based on this principle. These are heated to boiling, but do not curdle because the starch stabilizes the egg proteins. Other special types of custard dessert, such as the decoratively molded *bavaroise* (Bavarian cream) rely on gelatin to hold a firm shape. In the tropics, cow’s milk is replaced with that of water buffaloes, or by coconut milk. Some Chinese custards have a sugar syrup base, and the Japanese make savory *chawan mushi* using *dashi* stock as the liquid. Vanilla is the classic haute cuisine flavoring for custards, but the English use nutmeg on baked custards, the Spanish and Portuguese flavor with lemon and cinnamon, and the Chinese with fresh ginger.

In the complex history of custards and puddings, mixes are a relatively recent invention. Convenience was a factor in their development over time, but they must also have resonated with ideas about soft milky desserts from previous centuries. To disentangle these, one has to look at the European history of such dishes.

Baked egg and milk custards are of ancient origin; a Roman recipe of this type survives. The combination was also liked in the Middle Ages, when pastry was used to contain the mixture. The word “custard” comes from *crustade*, meaning a single-crust pie. Sugar, spices, vine fruit, almonds, and ground meat were added to custards. Little distinction was made between sweet and savory foods until the seventeenth century (the idea of a savory custard containing meat has survived into the twenty-first century as quiche Lorraine.) Possets, warm drinks of eggs, cream, wine or ale, sweetened and spiced, were also made. They were popular in the seventeenth century, and may have influenced ideas about custard as a dessert sauce, as well as being ancestors of egg-nogs.

With or without pastry, custards were popular in eighteenth-century Europe. In England, rich ones flavored with almonds, pistachios, or orange flower water were called creams. Lemon cheese, a mixture of lemon juice and rind, butter, sugar and eggs—almost a milkless custard—was popular for tartlets, as was egg custard. Custards also acquired a new role as a base for ice creams, which later became important in North America.

Elsewhere, elegant custard desserts developed, such as the egg yolk and cream *crème brûlée*, with a crust of caramel sugar, and *petits pots de crème*, cooked in little cups or *ramekins* (itself a Flemish word which originally meant ‘little cream’). Custards cooked in molds lined with caramel sugar—*crème caramel*, Spanish *leche flan*—later became clichés of restaurant cookery in the twentieth century.

The history of English puddings is obscure, but sixteenth century versions seem to have been sausage-like,

with meat and cereal fillings, ancestors of suet and plum puddings. Early eighteenth-century recipes included boiled custard puddings and quaking puddings of egg, cream, and flour. Both types were wrapped in cloths and boiled. These were all staple foods, as was hasty pudding, hot milk with flour stirred in to thicken it. Sweet baked puddings in pastry-lined dishes became fashionable, too; a custard done this way was sometimes called a custard pudding. Other recipes used fruit, nuts, vegetables such as carrots, or sweetened rice, barley, or sago with milk, cream, and eggs. Similar cereal mixtures with milk, sugar, and eggs were known elsewhere in Europe.

In early nineteenth-century America, ideas about custard and puddings were probably little different than those of the English. One influence at this time was the availability of easy-to-use starches such as arrowroot, tapioca, and potato flour, which gave a pleasing transparent appearance, and were used for invalid food. The critical development was the extraction of cornstarch in 1842 in New Jersey; by 1850, food-grade starch was being produced. Secondly, in Birmingham, England, in 1844 a pharmacist named Alfred Bird devised custard powder, a flavored starch mix, for his wife who was fond of custard but allergic to eggs. It is unclear if he used cornstarch (at that point, mostly used in laundries) or another type such as arrowroot or sago. Custard powder soon became popular in Britain.

American housewives continued to make puddings with cornstarch, milk, and eggs, using chocolate, vanilla, or fruit as flavors. Cooks also found that cornstarch “stretched” an inadequate egg supply and, added to custard, made it more stable. Recipes increased in number, and flavors increased—caramel, lemon, almond—recalling custards and puddings of other traditions and centuries.

Convenience puddings appeared in the mid-1920s, when the Jell-O Company introduced a chocolate mix for use in institutions. Surprisingly, in view of the move toward convenience foods, ordinary consumers had to wait until 1934 until they could buy a similar product, sold as Walter Baker’s dessert. Although the British used starch mixes for cold-molded blancmanges, they never took to pudding mixes. In contrast, in North America, other flavors soon appeared and the mixes were also marketed as pie fillings. Instant mixes came onto the market in the 1950s.

By this time, the defining characteristics of pudding seem to have emerged as softness and sweetness, echoing custards, batter, and milk puddings. Speed was also important, perhaps influenced, by the idea of hasty pudding, to which cornstarch puddings bear some resemblance when reduced to basic principles. Puddings and custards also converged as cornstarch mixes were increasingly used in pies. “Cream” pies have picked up elements of the sweetness and softness of custard and acquired a name associated with it, while maintaining a link, through cornstarch, with the cereal element so important in puddings.

Glass pyramid with cream or custard glasses. Mixed pieces from England and America, circa 1790-1800. The custards were cooked in a double boiler, then poured hot into the glasses, which were then stored away in a cool place until the custard set. The custards were brought to the table and served from the pyramid. The large glass on top is intended for a fruit or floral centerpiece. ROUGHWOOD COLLECTION. PHOTO CHEW & COMPANY.

Nutritionally, a standard egg custard provides about 380 calories, a little under 20 g protein and 17 g fat, plus about 170 mg calcium. The composition of richer custards or English puddings is infinitely variable, depending on the whim of the maker: more cream, more sugar, higher calories. Standard mixes and custard powder made up with whole milk provide about 90 calories per 100 g when mixed; most of the calories are from sugar and starch. The high-protein or low-sugar pudding mixes marketed in the United States as snacks and for dieters are a notion that would amuse the English originators of puddings, for whom it was, by definition, a high-calorie, filling food and an essential part of a proper dinner.

**CUTLERY.** For a very long time humans used their fingers to convey food to their mouths, tearing pieces off with their teeth, which had evolved for this purpose. Then they found that, by using small flakes of sharp-edged flint as cutting tools, they could skin and cut up the carcass of a heavy animal and remove the small pieces to a safer place to eat. Similarly, natural objects, such as shells, could be used to hold and carry water.

With the discovery and use of copper, humans moved into the age of metal. The early Egyptians, who already had very beautiful and skillfully executed flint knives, made copper knives that were small and leaf-shaped in design and may have been used for domestic or ceremonial purposes. These copper knives did not have as hard and sharp an edge as flint and probably did not replace the flint knives entirely until it was discovered that combining the soft copper with tin produced the much harder alloy of bronze. This extended the use of metal into everyday objects and gave bronze knives a hard and sharp edge; the distinct advantage of these blades was that they could be resharpened.

Further specialization of knives occurred throughout the Middle East and spread among the Celts of central and northern Europe in the Bronze Age. There are some extant small knives with considerable decorative style that were probably personal eating implements, perhaps carried on a type of chatelaine. Additionally, other larger and decorative knives, capable of being used for eating or defense purposes, were possibly carried in a sheath on a belt.

The next important advancement was the slow introduction of the use of iron, which started with meteoric iron in Egypt in the third millennium B.C.E. with very small improvement in the technology and was probably in the beginning not a great improvement on bronze.

During the Roman period, divisions of society appeared with their own rituals for eating and drinking. Some Roman illustrations show diners in a reclining position, which must have made cutting food with a knife quite difficult. Perhaps the food was cut into bite-sized pieces before serving, similar to the custom in most Asian countries today. The reclining style of eating was not for everyday, but for banquets and entertaining. Iron knives,

some with decorative bronze handles, were now common, and the Romans had a large range of knives to meet their various requirements, including specialized knives for eating and food preparation.

The Romans also developed folding knives with blades of iron, some with spoons attached, with decorative bronze handles showing hunting scenes of hounds chasing hares; another version of the folding type is a figure of a lion with an iron knife blade, folding spoon and sometimes a "spike," perhaps for eating snails. It is not inconceivable that these utensils were used and lost by legionaries moving around the country; they are among the more common Roman objects excavated in Britain.

There is evidence from Saxon grave sites of women and children having small personal knives of iron interred with them during the early centuries following the withdrawal of the Romans. Some of these knives reflect the style that was developed by Northumbrian monks. The larger knife, called a "scramasax," was a general-purpose iron knife having a very distinct shape and point, with a thick back and a blade that was sometimes inlaid with silver and brass in a wooden "bobbin" handle. Some of the better examples show great skill in the patterned inlay work on the blade. The scramasax became quite famous and popular throughout Europe; a well-recorded knife owned by Charlemagne is an example of its status. Some of the excavated medieval knives from the foreshore of the Thames still show this influence.

Illustrations from medieval manuscripts show rich tables set with ewers and bowls, a knife or two, and occasionally a fork. The number of knives on the table does not match the number of diners present, so, according to the custom of the time, the diner would carry and use his own knife and spoon, or perhaps share a knife provided on the table. The ewers and bowls were for cleansing the fingers before taking food from the communal dishes. A small fork was most likely provided for picking up preserved and sticky food. The fork was shared and, like the spoon, did not become an eating companion with the knife until after the second half of the seventeenth century. Most of these early forks are bronze and silver, with two tines, and have been excavated in Europe, particularly Italy. They did not change very much in style until the late sixteenth and early seventeenth centuries, when the number of tines varied from two to four. However, the two-tined fork, also in steel, lasted in common usage in western Europe, including Britain, until the twentieth century.

The personal carrying of knives is well illustrated by Bosch and later by Breughel, both of whom show knives worn in the belt ready for eating or, if need be, self-defense. Spoons were usually tucked into hats and clothing and were perhaps easily lost. This might explain the many spoons that have been excavated at the apparent crossing point of one of London's ditches where we can assume people dropped the spoons when they jumped and then failed to retrieve them.

Medieval travelers were expected to supply their own eating utensils at any lodging house or inn in which they stayed overnight. Most men carried a knife of some sort in their belts as a matter of course, but a rich traveler might have a more elaborate sheath, perhaps containing a large knife and an extra sheath containing a small eating knife and spoon. Later medieval knives were subjected to considerable innovation in both design and construction. The reason for this is not entirely clear, but one suspects that location, novelty, desirability, and profit were factors.

National styles were also appearing, although with so much trade and importation plus the movement of people, it is not always easy to determine where a particular excavated knife was made. The style and cutler's mark or other inscription might help to identify country or origin. Knives from the Thames foreshore would suggest that knives were frequently dropped overboard from visiting foreign ships and that local inhabitants were using the river as a highway and rubbish dump, thus increasing the difficulty of identification many years later.

Eating knives of the seventeenth century became thin and elegant and, toward the end of the century, were more decorative, with carved ivory figures and composite handles of jet, ebony, amber, colored bone, hardstone, agate, cut steel, and precious metal. Such knives were accepted as a decorative part of dress and were suitable as impressive gifts. Very few of the common knives have survived except in an excavated condition, whereas many of the fine-quality knives that were often given as gifts have survived and been handed down through the centuries.

A pair of knives given by the groom to his bride as a wedding gift was an indication of wealth. The bride then wore the knives as a token of her position as mistress of the house. This custom lasted until the early seventeenth century. Many other crafts were involved in the making of these quality knives. Although a cutler was required by his guild to make a complete knife, the handles were made by specialized craftsmen and even imported from abroad. The sheaths were made by experts in the field of leather, wood, fabric, and beadwork.

Parallel with the decorative knives was a type of knife that was very long and elegant; it was made of one piece of iron, and the handle was decorated with balusters and turning. These knives, with handles showing traces of black enamel, may have been given as "memento mori" presents.

The first half of the seventeenth century saw a change in the size and style of the knife. It was getting shorter, the point was removed (since it was no longer required as a spike to transfer food to the mouth), the blade was sometimes wider at the tip than at the bolster, and there was a short handle of a round tapering section in ivory, bone, or wood, sometimes decorated with inlaid wire. The result was a strong, very purposeful "prime" knife that matches the basic simple Puritan spoon of this

Plush-lined knife box with cutlery, showing a typical "scimitar" knife blade and fork with pistol handle. It was this distinctive knife that gave its name to the eighteenth-century "caseknife" bean, due to the similar shape of its pod. WILLIAM H. BROWN COLLECTION.

period, which has a plain, flattish oval bowl with a simple parallel-sided bar stem.

The early seventeenth century also saw the general introduction of a fork at all social levels, usually as a matching companion to the knife. Forks had been used in Europe from early times, perhaps among the Romans—after all, a trident is only a large-sized fork—and large iron forks had been used for many years as cooking implements. This is well illustrated in the Bayeux Tapestry, which shows a cook removing a piece of meat from a cauldron with a long wooden-handled "fleshing" fork. Travelers from abroad brought back from Italy the habit of eating with a fork—they were probably impressed with the novelty, not least the hygiene—and after some resistance, the custom was accepted in England. At first the style, construction, and material of the fork

Silver fork made in London and dated 1632, with the crest of John Manners of Haddon Hall. COURTESY OF THE VICTORIA & ALBERT MUSEUM.

matched that of the knife with the handle being slightly smaller in size and the tines of the fork made of steel. This continued to the middle of the seventeenth century when the spoon finally joined the knife and fork, giving us a typical Puritan knife, fork, and spoon.

The evolutionary design of knife blades goes through a line of many peaks and troughs throughout the centuries. The “peaks” throw up a perfect “prime” knife, highly suitable for its purpose; this depends on all the components’ being sympathetic to each other whether they were made by one or by many craftsmen.

However, another introduction of the fork emerged at the same time; this was in silver and was hallmarked in London, dated 1632, and engraved with the crest of John Manners of Haddon Hall. This simple one-piece silver fork was in the style that was current in Paris at that time and matched the very plain Puritan spoon used in Paris and London. This set the custom of a spoon and fork matching, with the knife following suit and later in the eighteenth century all three pieces came together in large services of various patterns.

During the latter part of the seventeenth century, traveling sets containing knives, forks, and spoons were still necessary and continued throughout this and the next century. Most of these sets consisted of a knife and fork in a slip case, some with spoons. Others were more elaborate, containing a folding or dismantling knife, fork, and spoons with a beaker, corkscrew, and perhaps other items. The sets were likely to be made to special order, making the container very compact.

With the restoration of the monarchy in 1660, the design of knives slowly changed from the rather severe Puritan knife. The blade became longer, very curved, and spatulate at the tip, and the handle had a distinct pistol shape. By the first quarter of the eighteenth century, it finally evolved into a prime example of a Baroque knife. The popular term for this type of knife is “scimitar,” and it can be found in all its stages, from its rudimentary beginnings to another “prime” knife of 1720. The silver-handled scimitar knife is very satisfying and comfortable to use and is a favored antique for the table even today.

Contemporary with this change of style and the practice of laying the table with matching knife, fork, and spoon was the introduction of the separate dining room with dining table and chairs and other furniture. Some of the wealthier middle-class merchants began to supply their guests at the table with cutlery from fishskin-covered boxes on the dining room sideboard that contained knives, forks, and spoons in quantity, thus making the carrying of cutlery by guests unnecessary.

One of the most prolific suppliers of this style of cutlery, and probably an early entrepreneur of the factory system using local labor, was the Master Cutler Ephraim How. He and his son John made cutlery first at Chingford, then at the Southend Mill, Lewisham, and sold it from their shop at Saffron Hill, London.

From 1720 the scimitar became debased with the straightening of the blade and a hump on the back, but it still retained the round spatulated end; the handle lost its pistol shape. All of this disappeared after the middle of the century when a change occurred in the evolutionary chain of the eighteenth-century knife with the introduction of the “French” style. This was consistent with all the other similar fashions in the second half of the eighteenth century.

Knife blades became long and spear-shaped with the point on the central axis and the widest section halfway

along the length of the blade. Handles were tapered with a round to oval section and sometimes capped with silver. Others were made of stamped silver with a raised foliate design, soldered together and filled with resin; they later became straight-sided and square using green-stained ivory, bone, or ebony.

Knife boxes continued to be used as pieces of quality furniture, holding a dozen or more knives and forks and sometimes silver spoons. Spoons in a larger variety of sizes, including servers, could be found in a separate box, that is, the middle box of a set of three. Most early- and late-eighteenth-century boxes had locks with keys and were kept in the dining room; the contents were washed *in situ* after each meal by the servants and locked away until required again.

It is about this time—1800—that dessert sets appeared; they were popular as gifts right through the nineteenth century. This was exploited by the cutlery trade, as knives have always been acceptable gifts.

There was no return to the evolutionary course of the design of the knife until 1820, when British style, after making weak attempts at bringing back the scimitar blade, settled for a large, parallel-sided blade with a rounded tip and a straight, simple handle made of ivory, stained green or plain, or of figured silver in many styles. This continued to the end of the nineteenth century with only small interruptions from the influence of various art movements and fashions that affected the decoration rather than the construction or size. Examples would be the influence of art nouveau and of gardening implements, such as serving utensils shaped like spades; the term “butter spade” is still in use.

Industrial exhibitions in this period were popular and fashionable and would have provided ample scope for displaying high-quality skills and innovations. During the early part of the twentieth century came a slow reduction in the size of the knife, along with corresponding changes in other pieces of tableware. The days of having to carry personal eating equipment were long gone, but with modern traveling by train and motor car, small folding fruit knives, cutlery for picnic hampers, and military and camping canteens were developed.

In 1914 there was an important change in the construction of the knife: stainless steel was commercially produced. Its application to knife blades was enormous. It meant that blades would no longer rust readily and would resist staining from acids and foods, both being the bane of most carbon steel blades.

There was one style of knife that appeared at the end of the nineteenth century and evolved slowly, both in England and in Germany. This was the all-metal one-piece knife in both iron and steel that had appeared at various times in the past and reappeared with the introduction of stainless steel. This knife is an obvious candidate for a “prime” knife of the first half of the twentieth century and, with the partnership of stainless steel spoons and forks, must have seemed the ultimate in cutlery. Such knives were produced in large quantities.

However, in recent times, industrial and silversmith designers have been involved in producing a proliferation of styles and novelties, perhaps to cause comment as well as to eat with.

**DAIRY PRODUCTS.** Dairy products are derived from milk, the secretion of the mammary glands of mammals, usually cows (bovine), sheep, goats, buffalo, mare, camel, or yak. Most dairy products originate from bovine milk and, to a lesser extent, sheep and goat milk. As milk contains approximately 80 to 90 percent water, it is prone to undesirable microbial growth with concomitant product deterioration. To prevent this problem from occurring, and to ensure a longer shelf life, milk is processed to form different products such as ice cream, cheese, milk powders, yogurt, butter, lactose, and anhydrous milk fat (also known as butteroil). Milk can be separated into a cream fraction and a skim milk fraction by a centrifugation technique called separation. This process concentrates the fat present in the milk into the cream phase, leaving a skim or partially skimmed phase with much lower fat content. Typical fat and water contents of selected dairy products are shown in Table 1. The speed of centrifugation can be adjusted to yield different fat content in cream. Milk processing applies different preservation techniques to allow for longer storage of dairy products. Milk powders are produced by concentration to remove some of the water, followed by atomization into a fine mist and drying at high temperatures. Heat and dehydration (water removal) are employed to give a long shelf life for milk powders. Ice cream is a dairy product preserved by the action of freezing. Yogurt and cheese are both fermented products. A bacterial culture is used to inoculate milk, for which the primary function is to lower the pH from 6.7 (typical for fresh bovine milk) to 4.2 for yogurt and in the range 4.6 to 6.0 for most

cheese varieties. The bacterial cultures also assist in breaking down proteins and fats in the milk product to develop some of the flavor. The preserving function of added bacterial culture is to compete with unwanted pathogens for nutrients. Thus cheese and yogurt are preserved by dehydration, acidification, and competition with pathogens for survival in the product.

### Heat Treatment of Milk

For food safety reasons, milk is often heat-treated prior to consumption or further processing. The most common heat treatments are holding at 162°F (72°C) for 15 seconds, called pasteurization, or at 145°F (63°C) for 30 minutes, called batch pasteurization. Both of these treatments have similar effects on killing undesirable microorganisms in milk. The treatment is sufficient to destroy two indicator organisms, *Mycobacterium tuberculosis* and *Coxiella burnetii*.

Another common heat treatment is to hold milk at 284°F (140°C) under pressure for 2 to 3 seconds, producing ultra high temperature (UHT) milk. This milk is essentially sterile and can be packaged in cardboard containers and stored at room temperature for up to six months with little microbial-induced deterioration. UHT milk is more commonly consumed in Europe than in Australia, New Zealand, or North America.

An alternative to preserving milk by heat pasteurization is high-pressure processing, where pressures of around 300–600 MPa are employed to rupture the membranes of pathogens and denature enzymes that cause de-

**TABLE 1**

#### Average composition of selected dairy products (grams per 100 grams of milk)

	Water	Fat	Protein	Lactose	Sodium chloride	Calcium
Cheddar cheese	37	32	24	0	1.6	0.8
Ice cream	61	10–14	3.6	22	0.2	0.15
Full-fat yogurt	89	3	3.5	7	0.15	0.1
Butter	16	81	0.9	0.06	0–1.2	—
Skim milk powder	3–4	1	35	52	1.3	1.3
Whole milk powder	2	27	26	38	1	0.9
Whey powder	4	0.6–6	80–93	1–7	3	0.8–2.2
Cream	55–80	12–40	1.8–2.6	2.5–4.5	0.01	0.1

terioration in milk quality. This process has not been adopted to any significant commercial extent as the milk must be processed in batch quantities rather than in a continuous fashion as in a pasteurizer. Gamma irradiation of milk for the purpose of preservation is not practiced as it tends to produce off-flavors. Ultraviolet light can be used to pasteurize milk, and has the additional benefit of increasing the amount of available vitamin D. Bactofugation is sometimes employed to remove bacteria in milk by a process of centrifugation. Hydrogen peroxide can also be used to improve poor-quality milk. This preservative can be removed by heating milk to 122–131°F (50–55°C), whereupon the enzyme catalase present in milk destroys the added hydrogen peroxide.

### Milk Composition

Milk contains proteins, fat, water, lactose, inorganic salts, and other minor organic material such as phospholipids, organic acids, enzymes, hormones, vitamins, nucleotides, amines, amino acids, alcohols, aldehydes, ketones, and esters. (A complete set of detailed compositional tables can be found in Noble P. Wong et al., *Fundamentals of Dairy Chemistry*, pp. 1–38.) An understanding of how the major constituents are structurally arranged in milk is necessary to predict how milk processing conditions affect flavor, texture, and the keeping qualities of dairy products.

The gross composition of milk varies according to the species of mammal, the breed of the cow (especially for bovine milk), and the stage of lactation. Note the relatively low amount of casein in human milk, rendering it difficult to make cheese. The breed of cow will affect the level of fat and protein. Holstein cows are common in dairies in North America, Australia, and New Zealand.

An important advancement in milk compositional study was the development of a rapid test for milk fat by Stephen M. Babcock of the University of Wisconsin in 1890. This procedure allowed for accurate marketing of milk, resulted in a more consistent quality of dairy products, and facilitated the development of better farming practices to optimize fat content in milk.

Milk composition and volume are affected by the season, particularly in milder climates such as Australia and New Zealand where cows are pasture-fed all year round. Milk production drops during the winter months of May to August in the Southern Hemisphere, to a level such that there is little excess milk available for dairy processing beyond that of market consumer milk. In the colder climates found in Canada and the north of the United States and Europe, cows are fed on silage during the winter months. This produces a more uniform supply of milk and often results in paler and less yellow-colored dairy products, especially butter and cheese, due to the lower levels of beta-carotene in silage feed. Fat and total milk solids (fat, protein, and minerals) are lower in summer months compared to winter in both hemispheres. The effect of pasture quality and quantity on milk composition is a complex issue. Feed quality is affected by the

level of roughage, fat, protein, energy level, and the fatty acid profile.

One important factor in milk quality that has important consequences in dairy processing is the health of the cow. Mastitis is an infection of the udder that results in high somatic cell counts in the milk. Immunoglobulin levels are higher in mastitic milk, whereas fat, lactose, casein, and whey protein levels are lower. Treatment for mastitis requires antibiotics; however, this has the undesirable effect of killing introduced bacterial cultures in the manufacture of cheese and yogurt. Milk processing factories rigorously and routinely check milk samples from individual farms for antibiotics, as well as for levels of fat, whey proteins, caseins, urea, and lactose. Milk containing antibiotics is discarded and a penalty fine may be imposed on the farmer. Routine testing also allows correct payment to be made to the farmer, usually based on the amount of casein plus fat. In addition, due to the variable composition of milk, testing allows batches of milk to be standardized to a particular casein or fat content depending upon the type of dairy product to be made.

### Milk Fat Globules

The fat in milk is emulsified with a membrane material consisting primarily of proteins, phospholipids, and enzymes. Other minor components of the membrane include glycoproteins, phospholipids, carotenoids (including beta-carotene), and sterols (including cholesterol). There are approximately 15 trillion fat globules in one liter of milk, with a size in the range of 0.1 to 20 micrometers. The membrane surface serves to protect the fat from undesirable oxidation. Fat globules will still cream given sufficient time. The creaming effect is accentuated by the agglutinin reaction, which results in fat globules clustering and rising rapidly to the surface to form a cream layer.

Approximately 98 percent of the fat in milk exists in the form of a triacylglyceride, where three fatty acids are attached to a glycerol molecule. The fatty acids comprise CH<sub>2</sub> methylene groups linked together to form a chain of varying carbon lengths. Milk fat has a significant proportion of fatty acids with a length of four carbon atoms (C<sub>4</sub>), known as butyric acid, which causes the sharp, acidic taste in some cheese varieties. This flavor is often described as rancid. Other major fatty acid components of the triacylglyceride include myristic acid (C<sub>14</sub>), palmitic acid (C<sub>16</sub>), stearic acid (C<sub>18</sub>), and oleic acid, which also contains 18 carbon atoms but differs from stearic acid in that it contains one unsaturated C=C bond.

Due to the many possible arrangements of different length fatty acids, the melting point of milk fat is not as sharply defined as for pure compounds, but rather extends over a wide range of temperatures. Milk fat is entirely solidified at –40°F (–40°C), and has melted completely at 104°F (40°C). At refrigeration temperature milk fat is between 40 and 50 percent solid, despite the apparent solid appearance at this temperature.

Milk fat, when solidified, crystallizes into three main forms (alpha, beta, and beta' polymorphs) depending upon the rate of cooling. Tempering of a food product containing milk fat is a process of careful adjustment of the temperature at different heating and cooling rates. This process promotes the formation of a particular polymorphic structure with desirable texture. Tempering is used in butter manufacture.

### Unsaturated Milk Fat

Butters, spreads, and margarines that are high in unsaturated fatty acid content are believed to protect against heart disease. Margarines usually contain a higher level than butter. The unsaturated C=C bond in oleic acid (and other unsaturated acids) can exist in two forms, the *cis* form where hydrogen atoms are on the same side as the C=C bond, and the *trans* form where the hydrogen atoms are on either side. The *cis* form is more common in nature and believed to offer better protection against heart disease.

Conversion of a polyunsaturated liquid oil to a higher melting point mono-unsaturated solid fat (such as in margarine manufacture) can take place by the process of partial chemical hydrogenation, where hydrogen atoms are added to some of the C=C bonds to form saturated C-C bonds. The process of hydrogenation requires the initial removal of polar lipids such as phospholipids, and heating the oil at 320°–428°F (160°–220°C) under a pressure of 2–10 atmospheres with a 0.01–0.2 percent nickel catalyst. Consumption of *trans* mono-unsaturated fatty acids has been associated with heart disease (see Beardsley, p. 34).

The degree of unsaturation is measured by the iodine test, where the number of grams of iodine reacting with the C=C bonds in 100 grams of oil or fat is determined. Generally, the higher the number of unsaturated bonds and the lower the carbon chain length, the lower the melting point of the fatty acid.

### Milk Fat Deterioration

Deterioration of milk fat can occur by two main mechanisms: fatty acid release and oxidation of C=C bonds. Release of fatty acids occurs by cleavage (hydrolysis) of a fatty acid from a triacylglyceride molecule. The presence and release of butyric acid will give the typical rancid flavor found in blue and Italian-style cheeses. Oxidation of C=C bonds results in formation of hydroperoxide radicals that form high molecular weight compounds over time with increased viscosity and propensity for foaming. This is more of a problem with vegetable oils used for frying where extreme temperature fluctuations take place. Oxidation is promoted by the presence of oxygen at high temperatures and high water activity.

Fatty acid hydrolysis is catalyzed by an enzyme called a lipase. Milk contains 1–2 milligrams per liter of a native lipase called milk lipoprotein lipase. This enzyme is 90 percent inactivated under pasteurization conditions.

Hydrolysis (more specifically lipolysis, in the case of oils) is exacerbated at higher pH, a temperature of around 37°C, by light, and by the degree of agitation of milk. Exposure of milk fat as a result of agitation will provide access by the milk lipoprotein lipase, and lipolysis will occur. Sufficient agitation of milk can occur during homogenization. If milk is not pasteurized prior to homogenization, enough lipolysis can take place, with release of fatty acids, to burn the throat of someone unfortunate enough to consume this milk. Needless to say, milk is always pasteurized before homogenization.

Milk obtained fresh from the cow is partially protected against lipolysis by the milk fat globule membrane, and also by the separation of milk lipoprotein lipase (largely bound to the casein micelles) from the milk fat substrate. As already stated, agitation of milk promotes lipolysis. Heating fresh unpasteurized milk to 86°F (30°C) then cooling back to refrigeration temperatures will cause rancidity to occur within twenty-four hours. This problem will occur if warm fresh morning milk is added to cooled evening milk from the previous day, then cooled back down again. In addition, spontaneous lipolysis occurs in one out of five cows after cooling milk to 59–68°F (15°–20°C). This problem is circumvented by mixing with four to five times the volume of normal milk. Freezing and thawing of milk can also promote lipolysis. A slower rate of freezing will increase the rate of lipolysis.

In the United States, whole milk powder from lipase-treated milk is used in the manufacture of milk chocolate to impart a slight rancid flavor note. This flavor is what the U.S. consumer has come to expect in milk chocolate flavor, presumably for historical reasons when low-quality and less expensive milk may have been used in the manufacturing process. This flavor is absent in milk chocolate produced in Europe, Australia, and New Zealand.

### Milk Proteins

Proteins in milk are broadly classified as either caseins or whey proteins. Caseins are mostly insoluble in water and exist in an aggregated form called a casein micelle of average size 0.2 micrometers. This is sufficiently small to scatter light and render to milk its white appearance. Whey proteins are soluble over a wide pH range and have high nutritional value.

Whey comprise the class of proteins that are soluble in milk. They are globular proteins of size 2–4 nanometers. The major subcomponents of bovine whey are  $\alpha$ -lactalbumin and  $\beta$ -lactoglobulin. Human milk does not contain  $\beta$ -lactoglobulin, and  $\alpha$ -lactalbumin is highly valued when extracted from bovine whey for use in powdered infant formula. Consumption of bovine milk or formula containing  $\beta$ -lactoglobulin may elicit an allergic response when consumed by very young infants. The main utility of  $\beta$ -lactoglobulin is as a gelling agent in food products such as comminuted meats. The presence of  $\alpha$ -lactalbumin will impair the gel structure formed from

## HOMOGENIZATION

Food products that contain fat and water phases must be emulsified to prevent creaming or sedimentation. In most biphasic dairy-based food products (with the exception of butter), water is the predominant phase, and the fat phase is emulsified. Emulsions are energetically unstable systems, and given enough time, will separate out into the two phases. This process is greatly hindered by covering the surface of the emulsion globules with some kind of surface-active component, commonly a protein, polysaccharide, and/or monoacylglyceride. Slowing down the rate of destabilization of an emulsion enables a food product to be stable over a period of weeks or months. Milk and cream are naturally occurring oil-in-water emulsions. Others include mayonnaise, spreads and dips, cheese, yogurt, sauces, ice cream, and salad dressing.

For fat to be broken up into small micrometer-size globules, energy must be supplied to the food product. This process is called homogenization. The types of homogenizers range from simple rapid and turbulent stirring devices, to more complex valve equipment that forms emulsions under high pressure, turbulence, and cavitation. A detailed overview of the different types of

homogenizers is given by Mulder and Walstra in *The Milk Fat Globule* (pp. 163–194) and by McClements in *Food Emulsions: Principles, Practice, and Techniques* (pp. 161–184).

As a general rule, the more energy supplied by a homogenizer, the smaller the fat globules formed, with a greater stability against creaming. Typical pressures for homogenization of milk in a dairy factory are 17 MPa first stage and 3.5 MPa second stage, the latter of which is used to break up aggregates of fat globules that may form in the first stage. This process produces globules of size 2–3 micrometers in bovine milk.

Other types of homogenizers that are not commonly used in dairy processing include ultrasonic and membrane units. Some of the effects of milk homogenization on dairy products include smaller fat globules as pressure increases, whiter colored cheese with higher moisture, increased viscosity of yogurt, increased lipolysis of milk, less oxidized off-flavors in milk, faster clotting of milk in cheese manufacture, and inactivation of the agglutinin properties (the agglutinin reaction causes clustering of fat globules).

$\beta$ -lactoglobulin, hence the requirement to separate these two components from whey.

Other components of bovine whey include bovine serum albumin, immunoglobulins, lactoferrin, and lactoperoxidase. Lysozyme is an enzyme found in milk that also has antimicrobial activity. This enzyme is found in higher concentrations in milk colostrum, protecting the gut of a newborn calf against invasion by pathogenic bacteria.

Colostrum is the initial secretion of the mammary gland after birth and contains a much higher casein and whey protein concentration than milk at later stages of lactation. The level of lactose is less than in milk, and the amount of fat is slightly higher. Colostrum confers immunity to a newborn calf through the high levels of immunoglobulins, and also provides a high-quality nutritional diet.

Whey is the main by-product of cheesemaking. It has historically been considered to be of low value, and used as pig food, fertilizer for agricultural fields, or simply disposed of into the ocean. Now, whey is spray-dried to produce a powdered protein ingredient, highly valued by the food processing industry for its excellent nutritional and textural modifying properties. Whey can be further fractionated into components that are spray-

dried, and these command a premium price for food and pharmaceutical applications.

### Functional Properties of Whey Proteins

Functional properties of whey proteins include its water solubility, viscosity modification ability, gelation, texturization, high nutritional value, flavor-binding, foaming, emulsification, fat and water retention, and control over shrinkage in products such as yogurt and gelled foods. The high solubility and excellent nutritional properties allow whey proteins to be used to fortify high-energy sports beverages. Increasing the viscosity of fluid food products by whey protein addition will affect the sensory properties, and reduce the tendency for particulate matter (if present) to sediment. Different types of gels can be created by heating  $\beta$ -lactoglobulin. The pH, concentration and types of mineral salts present, and the rate of heating will affect the properties of the gel, such as opacity, elasticity, and the propensity for shrinkage with expulsion of liquid during storage (syneresis). Gels that are formed far from the isoelectric point (around pH 5.5, where there is no average net charge on the whey proteins) will tend to be less opaque, more fine stranded, and more elastic.

Texturization of whey proteins is achieved by heating to form a coagulum followed by extrusion though

small diameter holes under high pressure to align the protein fibers. These can be further processed between heated rollers to remove more moisture, promote adhesion, and increase the toughness and chewiness. Textured dairy proteins have an application in forming vegetarian meat-like products.

Food products that contain oil require stabilizers to emulsify the oil and prevent excessive separation from the water phase. Both whey proteins and caseins can perform this function by homogenization to create small oil globules coated with proteins. Generally, the smaller the globules, the more stable the food product will be against creaming or oil separation. Examples of this type of food product include salad dressing and mayonnaise. Most oil and water food products are emulsified such that the oil globules are suspended in the water phase. If the oil or fat content is too high, a phase inversion takes place where water droplets are then suspended in the oil phase. In this case, whey proteins have little efficacy to act as emulsifiers. An example of a water-in-oil emulsified food product is butter.

Foam formation and stability are important attributes in food products such as ice cream, cappuccino coffee foam, meringue, marshmallow, mousse, and bread. Air bubbles are induced by rapid whipping and are lined with stabilizers to prevent rapid collapse of the foam. Whey proteins are excellent foaming agents, and their ability to unfold (denature) and cross-link at the air-water interface provides for good foam stability. Strong protein-protein interactions, such as that which occurs near the isoelectric pH of around 5.5, will promote foam stability. Free oil will cause a decrease in foam stability, which is the reason egg yolks (containing oil) are separated from egg white (containing proteins capable of stabilizing the foam) prior to whipping of the egg white. Emulsified oil, such as in milk or cream, will not affect foam stability to the same degree, as the oil is coated by the native milk fat globule membrane and does not come into direct contact with the protein foaming agents in dairy foams. However, if the native membrane is ruptured, perhaps due to enzymatic action or excessive turbulence when pumping milk during processing, the foaming ability is impaired. This is often a seasonal occurrence in some countries, creating cappuccinos with poor foams at certain times of the year when enzymatic activity is more pronounced. Special cappuccino milk is sometimes sold containing a higher proportion of added spray-dried foaming whey proteins to alleviate this problem. Further details about functional properties and emulsions are provided by Walstra in *Food Chemistry* (pp. 95–155).

### Calcium Phosphate in Milk

The major mineral component in milk (and most dairy products) is calcium phosphate, an inorganic salt of low solubility in water. A high intake of calcium in the diet is believed to promote strong bone development, hence the

recommendation of calcium in the diet of young children. The low solubility of calcium phosphate in water (and also in milk) would result in calcification, or boiler-scale, in the mammary gland if it were not for the unique properties of the casein micelle in solubilizing this mineral.

Each of the four main casein molecules ( $\alpha$ -s1-casein,  $\alpha$ -s2-casein,  $\beta$ -casein, and  $\kappa$ -casein) contain at least one phosphate group that is capable of binding to the calcium phosphate mineral complex in milk. Some twenty-five thousand of these casein molecules, with bound calcium phosphate, aggregate to form the heavily hydrated casein micelle of molecular weight 108–109 Daltons. Thus calcium phosphate is rendered soluble in milk (as the casein micelle itself can exist in milk as a stable suspension) and can be considered to be the binding agent that holds the micelle together. There is some controversy over the nature of the substructure of the casein micelle. The two main competing models are described by Pieter Walstra (1999) and Carl Holt and David S. Horne (1996).

### Formation of Milk Curds

Cheese and yogurt making has been in existence for thousands of years. Milk would have been carried around in the warm Middle Eastern climate in sacks made from animal skins, such as the stomachs of ruminant animals. Milk stored in a sack made from the fourth stomach of a young calf and carried around at temperatures in excess of 68°F (20°C) would eventually coagulate and separate into curds and whey given sufficient mechanical disturbance. The curds would have provided a nourishing meal and the whey a refreshing and nutritious beverage. This process has evolved into the highly scientific and mechanized approach used today in modern cheese-making plants.

The casein micelle will undergo extensive aggregation as the pH approaches the isoelectric point. For caseins in milk, this occurs at pH 4.6. This is the basis for the coagulation of milk and separation of the curds from the whey to make cheese. A comprehensive treatment on the physical chemistry of curd formation and subsequent reactions is given by Dalgleish (pp. 69–100), Green and Grandison (pp. 101–140), and Walstra (pp. 141–191) in Patrick F. Fox, ed., *Cheese: Chemistry, Physics and Microbiology*.

Curds are composed of aggregated casein micelles and trapped fat globules within the protein matrix. The whey phase contains mostly water with soluble minerals, whey proteins, and lactose. Casein micelle clotting (with consequent curd formation) can also occur by addition of coagulating enzymes or 20 percent alcohol. Most cheese varieties are manufactured by enzymatic coagulation, with some formed by acid precipitation to pH 4.6. Acidification can also take place by the addition of bacterial culture, directly by addition of acids such as hydrochloric, sulfuric, or lactic acids, or a combination of bacterial culture and direct acidification. Most bacterial cultures used in fermented dairy products are classified as lactic

acid bacteria, as they are capable of metabolizing lactose present in milk into lactic acid. This will lower the pH of milk and aid in the formation of a milk clot.

Casein micelles are prevented from forming a rapid milk clot in fresh milk by the presence of a hairy layer of adsorbed  $\kappa$ -casein molecules on the surface of the micelle. The  $\kappa$ -casein prevents the close approach of micelles at the natural pH of milk (6.7) by a mechanism known as steric stabilization. Both acid and alcohol addition cause a partial flattening of the  $\kappa$ -casein hairy layer, allowing coagulation to occur. Acid coagulation occurs via an electrostatic attraction mechanism, and alcohol coagulation by hydrophobic interaction. Casein micelles have sufficient inherent hydrophobicity to cause aggregation to occur in much the same way as hydrophobic oil droplets will coalesce, once the  $\kappa$ -casein layer has been flattened or removed.

### Milk Clotting Enzymes

The enzyme present in the fourth stomach of a calf, chymosin, is extracted by maceration of the stomach lining in a salt solution. The purified salt solution containing chymosin is called rennet. Chymosin will cleave the  $\kappa$ -casein hairy layer on the casein micelle at a very specific location, between the phenylalanine and methionine amino acids at positions 105 and 106 in the primary sequence of the protein. This cleavage point is fortuitously located at the point where the  $\kappa$ -casein molecule extends away from the micelle surface to form the hairy layer. Chymosin is therefore capable of removing the  $\kappa$ -casein steric stabilizing layer, allowing micelles to coagulate and form a curd, such as found in yogurt and cheese.

As the demand for chymosin is greater than the supply of calf stomachs, other enzymatic methods to coagulate milk have been investigated. An enzyme called pepsin, extracted from the stomach lining of pigs, calves, and chickens, has some efficacy; however, cheese made from this enzyme is often too soft due to excessive protein degradation. Often, rennet extracts contain a proportion of bovine or porcine (from pigs) pepsin in addition to bovine chymosin.

Enzymes extracted from fungi, bacteria, and plants can also be used to coagulate milk. Plant coagulants can be extracted from papaya, figs, pineapple, kiwi fruit, and *Cynara cardunculus* (cardoons and artichokes), a thistle which in Portugal is used to make Serra cheese. Most enzymes derived from plant sources are highly proteolytic (capable of extensive degradation of proteins) and non-specific in their action on proteins. The resultant small peptides, which are the degradation products of enzymes acting on proteins, produce a soft and pasty cheese with bitter flavor unless other steps are taken to circumvent these problems. Bitterness in cheese is correlated with higher amounts of hydrophobic peptides.

An increasingly common method to produce milk coagulant for cheese and yogurt manufacture is by recombinant DNA technology. The gene for expressing

chymosin is spliced into the DNA sequence of bacteria, such as *Escherichia coli*, which is then grown in a reaction vessel to levels that permit the extraction and subsequent purification of chymosin.

### Endogenous Milk Enzymes

The main native milk enzyme that hydrolyzes proteins is plasmin. This enzyme is located in the casein micelle, and therefore concentrated in cheese during the manufacturing process. Plasmin will hydrolyze proteins during cheese ripening and contribute to texture and flavor development. It has an optimum activity at pH 7.5, hence the term alkaline protease, and at 99°F (37°C). Pasteurization has an effect of increasing the total plasmin activity, as the otherwise inactive precursor, plasminogen, is activated. Plasmin itself can be inactivated by heating at 176°F (80°C) for ten minutes.

Alkaline phosphatase is another enzyme present in milk, and is inactivated by pasteurization. A test for alkaline phosphatase activity is used to determine if milk has been pasteurized, as the conditions of inactivation mirror those of pasteurization. This enzyme is preferentially adsorbed onto the surface of fat globules.

It is interesting to note that enzymes in milk are often segregated away from their respective substrates, thus preventing rapid deterioration of milk. Alkaline phosphatase reacts with the phosphate ester groups in the casein micelle, and would result in micelle disintegration if the enzyme were located there. In the same fashion, lipases are often found adsorbed into casein micelles away from the milk fat substrate.

### Lactose, the Milk Sugar

Lactose, also known as milk sugar, is a disaccharide molecule comprising two simple sugars (glucose and galactose) linked together. This sugar is rarely found outside of dairy products, unless specifically added. Lactose crystals present in dairy products, particularly ice cream, can cause a sandy texture if the crystals are too large.

Lactose must first be hydrolyzed by the enzyme lactase into glucose and galactose before it can be further metabolized in the human body. If lactase is absent from the body, a common occurrence among adult Asians and Africans, digestion problems may arise after consuming milk. These problems are referred to as lactose intolerance, and for this reason, milk is not usually consumed by adults from these two racial groups. Lactose is water-soluble, therefore largely absent in high-fat dairy products such as butter, butteroil, and ghee. In aged, fermented dairy products such as cheese, all of the lactose is metabolized by lactic acid bacteria into lactic acid within the first three to four weeks, so consumption of this product will not cause lactose intolerance. Even freshly consumed cheeses such as cottage and cream cheese are low in lactose. Lactose intolerance is discussed in Wong et al., *Fundamentals of Dairy Chemistry* (pp. 328–330).

## LACTOSE INTOLERANCE

Lactose intolerance is a disease characterized by symptoms such as abdominal cramps, bloating, and diarrhea, brought about by the inability to metabolize lactose. This condition is more prevalent among Asians and Africans. It is not a normal occurrence among young children, and the incidence rises as age increases.

Lactose, often called the milk sugar, is primarily found in milk. The level in bovine milk is around 5 percent. This relatively high concentration means that digestion of milk can be a problem for people who suffer from this disease. Lactose is a disaccharide consisting of a glucose and a galactose molecule joined by a glycosidic covalent bond. In normal digestion, an enzyme called lactase will hydrolyze lactose, producing glucose and galactose, which are subsequently further metabolized in the body. People who suffer from lactose intolerance lack this enzyme. The onset of symptoms is related to the level of lactose ingested. Small amounts of milk may not be a problem for some people who would otherwise suffer from lactose intolerance.

Lactose is found in relatively large quantities in milk, ice cream, and other nonfermented milk products. It is not usually found in matured cheese. Very small amounts

may be found in yogurt and fresh cheeses, such as cottage or cream cheese, but probably not sufficient to cause lactose intolerance symptoms. Digestive complaints after consumption of pizza is most likely due to the high amount of fat in this food, rather than the presence of lactose, which is barely present at all.

A remedy to aid digestion is to consume lactase in liquid form or as a tablet. An alternative solution is to manufacture low-lactose milk by the addition of lactase during processing. This step will produce a much sweeter milk, as both glucose and galactose are sweeter than lactose. To prevent the problem of excessive sweetness in milk, lactose levels must be reduced before the hydrolysis step takes place. Other more novel techniques involve adding lactic acid bacteria to cold milk; the bacteria remain dormant until the milk is consumed and warmed up in the body. They then metabolize lactose in the human gut. Another processing technique utilizes encapsulated lactase added to milk. The microcapsules remain intact at the low temperature and pH of milk during storage. After consumption, the higher temperature and lower pH rupture the lactase microcapsules, allowing lactose hydrolysis to take place.

### Browning Reactions in Milk

Two types of browning reactions occur in food products, enzymatic browning and the non-enzymatic Maillard reaction. The Maillard reaction is the more relevant of the two in dairy products, and is initiated by reactions between the amine part of a protein with sugars such as lactose. This reaction is inhibited at lower moisture content, pH below 6, and lower temperature. Besides the color change in some processed dairy products, there is also a nutritional consequence to the Maillard reaction. An important amino acid in milk proteins, lysine, contains an amine group that can participate in the Maillard reaction, resulting in a loss of bioavailability of this amino acid.

### Goat and Sheep Milk

It is of interest to note that the average size of fat globules in goat milk is slightly smaller (2 micrometers) than bovine milk (2.5–3.5 micrometers), and that the agglutinin reaction does not occur in goat milk. This latter effect is the primary reason for the scarcity of goat cream and butter on the market today, as the fat globules will not rise to the surface to the same extent as in bovine milk. Before the advent of centrifugal separators, it would not have been possible to obtain large amounts of cream

from goat milk. Most goat milk is processed into cheese, rather than into yogurt or consumed fresh. A component of goat milk fat, 4-methyloctanoic acid, is responsible for the “billy-goat” flavor of goat milk cheese.

Sheep milk has almost twice as much fat and protein, and slightly more minerals (ash), than bovine milk, and contains a higher proportion of immunoglobulins so is more resistant to unwanted microbial growth. The fat in goat and sheep milk is whiter than in bovine milk due to a lower amount of  $\beta$ -carotene, and contains a higher proportion of the medium chain length fatty acids  $C_6$ – $C_{12}$  that provide a better and more rapidly utilized energy source than the more common longer chain fatty acids. The suckling period for young kids and lambs is three to six weeks, and the milking period extends for a six-month period in spring and summer.

The volume of goat and sheep milk obtained in traditional sized family-owned farms or nomadic flocks is 40–100 liters per year. In contrast, commercial goat and sheep milk farms produce about 400–600 liters of milk per year. By comparison, 4,000–7,500 liters per year are obtained from bovine cows in commercial dairies.

The milk fat globule membrane is more fragile in goat milk compared to bovine milk, therefore there is a

## MILK NUTRITION

It is not always true that altering the dietary intake of fat, containing cholesterol, will alter the blood cholesterol level. Other factors such as the total diet, genetics, and exercise play an important role. The level of cholesterol in milk fat is 0.35 percent, whereas the level in milk is about 0.014 percent. Cholesterol levels in human blood average around 200 milligrams per 100 milliliters. Milk fat contains as much as 25 percent *cis* 18:1 fatty acid, one of the healthy fatty acids thought to help prevent heart disease.

### **Vitamins**

All of the essential vitamins are found in milk, although in some cases the amount is not sufficient to meet the recommended daily allowance. Vitamin C levels are reduced by approximately one half under pasteurization conditions; however, this is of limited concern, as milk is such a poor source of this vitamin. Folic acid and thiamin (vitamin B<sub>1</sub>) are reduced by around 10 percent during pasteurization. The water-soluble vitamins (B and C) are largely lost into the whey during cheesemaking, whereas the fat-soluble vitamins are concentrated, although some molds are capable of synthesizing vitamin B in mold-ripened cheeses. Riboflavin has an orange color that is more evident in skim milk than whole milk, and can be seen very clearly if fat and protein are removed from milk by membrane filtration. A vitamin A precursor, beta-carotene, gives milk fat its characteristic yellow color.

Milk is an important source of vitamins A and D, the latter due largely to fortification, which is common in the United States. Vitamin D fortification came about as a result of research performed by Harry Steenbock at

the University of Wisconsin in 1924, and is largely responsible for the virtual elimination of the bone disease rickets, caused by a vitamin D deficiency. Milk is otherwise a poor source of vitamin D; however, it assists in the absorption of dietary calcium. Vitamins A and B were first discovered by Elmer V. McCollum of the University of Wisconsin; vitamin A was identified in butter fat in 1913, followed later by the discovery of vitamin B in cheese whey.

### **Minerals in Milk**

Dairy products are a good source of many minerals, particularly calcium (see Table 1) where it furnishes about 75 percent of the dietary need in the United States. The bioavailability of calcium from milk products is around 85 percent, compared to 20–75 percent from vegetable sources. Low calcium dietary intake is generally recognized to contribute to osteoporosis and to predispose people to hypertension when consuming large amounts of salt. Bone mineralization requires a ratio of calcium to phosphorus of between 1.3 and 1.5 to 1, such as found in dairy products. Other nondairy sources of calcium have a much lower ratio.

Other trace elements of nutritional importance found in milk include iodine, which is required for thyroid hormone production, magnesium for energy-requiring biological functions, and zinc for the function of some enzymes in the human body. Bovine milk is a poor source of dietary iron; infants can develop anemia if not breast-fed with human milk (which contains a higher bioavailability of iron compared to bovine milk) or if other dietary sources are not found.

greater propensity for development of off-flavors. Goat milk is also more liable to undergo spontaneous lipolysis at 39°F (4°C). Further information on the processing of goat and sheep milk is provided by Frank Kosikowski and Vikram V. Mistry in volume 1 of *Cheese and Fermented Milk Foods* (pp. 297–313).

### **Liquid Milk**

Consumer milk is often sold in the United States according to the percentage of fat: 1 percent, 2 percent, whole milk (about 3 percent), and skim (less than 0.5 percent fat). The shelf life is usually around two weeks. The milk can be fortified with vitamins A and D. Full fat milk is often simply referred to as Vitamin D milk in the United States. Frozen milk may be stored for several months before use; however, it is prone to fat separation, lipolysis, and curd formation.

Flavored milks are becoming increasingly popular as a nutritious beverage, particularly among young people. These drinks are often low in fat with added stabilizers (such as guar and carrageenan) to compensate for the loss in creaminess. An unfortunate problem with gums and stabilizers is that drinks can frequently take on a viscous and elastic texture if too much is added. A wide range of flavors are added to milk, particularly in Australia, where chocolate, coffee, caramel, strawberry, banana, and vanilla are very popular. These have never reached the same level of popularity in North America.

### **Yogurt**

Yogurt probably originated in the Middle East, where goat and sheep milk was soured by the presence of naturally occurring bacteria. It is a favorite food in India, where it is unflavored and made from the milk of buf-

falo. Its consumption in India signifies the end of the meal. Plain yogurt is often used as a garnish in Middle Eastern meals. A discussion on yogurt manufacture is given by Kosikowski and Mistry in volume 1 of *Cheese and Fermented Milk Foods* (pp. 87–108).

Lactic acid bacteria (a 1:1 ratio of *Lactobacillus delbrueckii* ssp. *bulgaricus* and *Streptococcus thermophilus*) convert lactose to lactic acid in milk, lowering the pH from 6.7 to around 4.2 and giving yogurt its characteristic clean, acid taste. Often fruit and fruit flavorings are added to make yogurt into a dessert or snack product. The reduction in pH by added bacterial culture, along with refrigerated storage, contribute to the preservation of yogurt. The most common form of yogurt is a smooth viscous liquid; however, it can be frozen and served as a nutritious and refreshing yogurt-based beverage. The trend in the United States is for reduced fat (or nonfat) yogurt, more so than in Europe. The fat content in North American yogurt is typically around one percent.

To enhance the creaminess sensation of reduced or nonfat yogurt, polysaccharide stabilizers such as gelatin, pectin, or locust bean gum are often added, although they are not entirely successful at mimicking fat. These stabilizers have the additional function of reducing syneresis, the clear yellow liquid (whey) that appears on the surface of yogurt due to partial shrinkage of the casein protein network. Probiotic cultures, such as *Lactobacillus* species (*casei* and *acidophilus*) and *Bifidobacterium* species can be added to yogurt and also to milk protein-based beverages. The combination of bacterial cultures, including probiotic cultures, found in yogurt has long been believed to provide good health. This may explain the relatively large number of centenarian inhabitants of the Caucasus region in southwest Asia, who consume large amounts of yogurt.

Milk for yogurt manufacture is firstly standardized to the appropriate fat and protein level (commonly 12–15 percent total solids and 1–2 percent fat) using skim milk powder. The milk is heated at 185°F (85°C) for thirty minutes, or alternatively, 194°F (90°C) for forty to sixty seconds. The stabilizers are next added, followed by homogenization at 7 MPa and cooling to 86–113°F (30°–45°C). Bacterial cultures are added, fruit puree is mixed in if desired, and the milk is allowed to set for sixteen hours to form a coagulum before refrigerating to 39°F (4°C) and packaged for consumption.

Homogenization of milk prior to yogurt manufacture increases the viscosity of yogurt and inhibits the formation of syneresis during refrigerated storage. The shelf-life of yogurt at 39°F (4°C) is from thirty to sixty days. The two main types of yogurt are stirred and set. In set yogurt, milk is allowed to coagulate to form the yogurt network structure without mechanical disturbance. In stirred yogurt, the coagulated milk is stirred while cooling down, then the fruit puree is added if required.

Yogurt cheese is prepared as for other types of yogurt in the initial stages of manufacture, except that *Lac-*

*tococcus lactis* bacterial culture and rennet are mixed with the milk one hour into the setting period, and a cheese similar to cream cheese is manufactured.

### Cream and Sour Cream

Cream is produced by separating milk into a skim phase (with less than 0.5 percent fat) and a cream phase. The fat content of the cream increases with the speed of the separator. A separator consists of concentric stainless steel cones rotating at high speed. Fat in cream can vary from as little as 10–12 percent in half-and-half, popular in the United States, to 30–40 percent in table cream and whipping cream. Plastic cream can contain up to 80 percent fat. Off-flavors can be removed from milk and cream by the process of vacreation, where steam is injected into the product and removed, along with the unwanted flavors, under a partial vacuum.

Sour cream is produced by lactose acid bacteria fermentation or direct addition of mineral acids to cream. Fresh cream is first standardized to 20 percent fat, homogenized at 20 MPa and 160°F (71°C), pasteurized at 165°F (74°C) for thirty minutes, cooled, and then inoculated with bacterial culture. Rennet can be added to produce a firmer product. The fermenting cream is incubated for sixteen hours at 72°F (22°C) until a pH of 4.5 is reached, then cooled and packaged. The shelf life is three to four weeks. Condiments such as blue cheese, seafood, and onion can be added to sour cream to produce a dip.

### Ultra High Temperature Milk

Ultra high temperature (UHT) milk is produced by heat-treating milk at 284°F (140°C) for two to three seconds, essentially sterilizing the milk. It is packaged aseptically and stored at room temperature for up to six months. The two main methods of producing UHT milk are direct steam injection, and indirect heating by passing milk over a stainless steel surface that is heated by high pressure steam. UHT milk is characterized by a cooked flavor that dissipates over time and which is then replaced by a stale oxidized flavor that develops during storage. Another potential problem with UHT milk is that it is susceptible to gelation and sedimentation. The chemical and physical mechanisms for this are unclear.

Some work has been done using a spinning cone column to eliminate undesirable flavors from UHT milk. This technology utilizes a series of rapidly rotating concentric cones through which milk or cream can be passed down. Low temperature steam under a partial vacuum is passed up in the counter-current direction, which strips flavor components from the dairy product. The steam can be condensed and the flavor compounds distilled and kept for later use. This process can be used to remove feed-related off-flavors from milk, the oxidized flavor from UHT milk, or to strip desirable buttery flavors from cream for subsequent addition into low-fat dairy products.

## Buttermilk, Butteroil, and Ghee

Buttermilk is a by-product of churning in butter manufacture. It is low in fat (about 1 percent), and rich in the phospholipid and protein components at the milk fat globule membrane layer. Milk fermented with lactic acid bacteria and subsequently separated into cream can be used in the manufacture of cultured or ripened butter. Cultured buttermilk is derived from cultured butter.

Butteroil is produced by centrifuging liquid butter to a fat content in excess of 99 percent, the remainder being mostly water. This product is solidified at room temperature. A higher grade, at more than 99.8 percent fat, is called anhydrous milk fat.

Ghee is a product similar in composition to butteroil and used for confectionery manufacture and for cooking in India, and in Egypt where it is called *samma*, or *samm*. Buffalo milk is boiled for one hour, the curd skimmed off, and churned for thirty minutes to form a butter. This is heated and strained to yield ghee, a clear oil with a characteristic cooked odor and flavor.

## Other Milk Products

Kefir is an alcoholic, carbonated milk-based beverage popular in eastern and central Europe. Yeast and bacteria convert lactose into lactic acid, carbon dioxide gas, and alcohol (ethanol) overnight at ambient temperature. The levels of lactic acid and alcohol are around 1 percent each. Koumiss from central Asia is similar to Kefir but made from mare's milk, and has a higher alcohol content of 2.5 percent. Other nonalcoholic fermented milk beverages include acidophilus milk, and Bulgarian buttermilk with a comparatively high lactic acid content of 2–4 percent.

## Evaporated and Condensed Milk

Concentrated milk can be produced by partial evaporation of water to yield either evaporated or condensed milk. The removal of water is done by heating under reduced pressure to avoid excessive heat damage to proteins. Evaporated milk is sterilized and aseptically packaged, whereas condensed milk does not have this extra heat treatment step. Variations of condensed milk include sweetened, where 18 percent sugar is added to milk before evaporation, and condensed skim milk.

## Whey

Liquid whey is an orange-colored liquid comprising about 5 percent lactose, 0.7 percent whey proteins, and 1 percent minerals. The disposal of whey has always been an issue in the manufacture of cheese due to the large volumes produced. Approximately 90 percent of the volume of milk is removed as whey when making cheese. The high biological oxygen demand of whey prevents disposal into lakes and streams, where it can deprive fish of oxygen.

Whey proteins are very nutritious and have a high protein efficiency ratio (ratio of weight gained to weight of protein consumed). Fruit juices can be fortified with

around 6 percent acid whey powder to increase the nutritional value without adversely affecting flavor and color. Whey powder is highly water-soluble and adds vitamins, minerals, and high-quality nutritional proteins to other food products.

Liquid whey can be manufactured into cheese by adding milk or cream and then concentrating by evaporation. Cheese made by this method includes Brunost, Mysost, Gjetost, and Primost, which are popular in Scandinavian countries. The last two of these cheeses are made from goat whey. Ricotta is a whey-based cheese made by heating acidified bovine milk.

## Whey Protein Powder

The two main types of whey are acid and sweet whey. Acid whey is obtained by addition of acids such as lactic, phosphoric, hydrochloric, sulfuric, and acetic to skim milk, reducing the pH from 6.7 to 4.6 and causing the casein to precipitate (which is then removed). Milk has a very high buffering capacity, requiring large quantities of acid to reduce the pH to this level. Acid whey contains very little lactic acid, as curds and whey are separated without the fermentation step.

Sweet whey originates from the cheese manufacturing process. Curds and whey are separated at a pH of approximately 6.2 in cheddar cheese manufacture, therefore sweet whey from this cheese is less acidic than acid whey. Sweet whey from cheesemaking contains around 0.5 percent fat. Whey from cottage cheese contains little fat, and around 0.4 percent lactic acid as a greater amount of fermentation of lactose to lactic acid takes place before the curds and whey are separated.

Sweet whey contains an additional protein fragment, the glycomacropeptide (GMP), which originates from the surface of the casein micelle as a consequence of enzymatic hydrolysis during the milk clotting reaction. The presence of GMP affects the textural functionality of whey powder when used as a food ingredient. GMP does not contain the amino acid phenylalanine, which can cause brain damage in children suffering from the disease phenylketonuria, an inability to metabolize this amino acid. There has been some research done on the extraction of GMP from sweet whey for use as a protein source for phenylketonurics.

Fractionation of whey into components with very specific nutritional, textural (functional), and pharmaceutical properties is a burgeoning field of research with the potential of large profit margins for the dairy industry. Components of whey that inhibit microbial growth include lactoferrin, lactoperoxidase, lysozyme, and various immunoglobulins. Lactoferrin binds iron necessary for microbial growth. These antimicrobial agents have the potential for use as “natural” preservatives in food products.

Sweet whey from cheesemaking is first clarified to remove casein particulate matter, then separated to re-

## WORLD DAIRY MARKET

The three largest export regions of dairy products, with the percentage of the total world dairy market in 2000, were the European Union (36 percent), New Zealand (31 percent) and Australia (16 percent). Australia and New Zealand each account for around 2 percent of the world's production of milk. Due to their relatively low populations, most of the milk in these two countries is processed and exported, hence the apparent over-representation in the export market.

The major export products on the international market are milk powders, cheese, and butter. There is no economic gain in exporting fluid milk as most of this product consists of inexpensive and readily available water, hence the development of the dairy processing industry to create products with lower water contents.

According to the United Nations Food and Agriculture Organization, the total volume of milk produced in the world in 1996 was around 550 billion liters, of which about 12 percent comes from buffalo, sheep, and goats. The two largest milk producing regions in 1996 were the European Union, with 24 percent of the world's production, and the United States with 15 percent. The United States accounts for only 4 percent of the export market.

Milk production per cow per year is around 4,500 liters in Australia, where cows are pasture-fed, and increases to 5,000–7,500 liters in Europe and North America where supplemental feed is given. The volume of milk per cow can be increased by administering a hormone, bovine somatotropin, a practice allowed in the United States, but not in Australia or New Zealand.

Dairy product commodities are subject to large price fluctuations on the international market. To even out the price instability, and to support the local dairy industry, governments (particularly in the European Union) heavily subsidize milk prices. This has resulted in a surplus of some dairy products.

According to the Australian Dairy Corporation (1996), consumption of milk is highest in Ireland and the Scandinavian countries at about 150 kg per person per year. Butter consumption is highest in France, Germany, and New Zealand at around 7–8 kg per person per year. Cheese is most popular in Germany, France, Italy, and Greece, the inhabitants of which consume around 20 kg per person per year. Consumption of yogurt is highest, at around 20 kg per person per year, in France and the Netherlands.

move most of the fat. The whey is initially concentrated to around 40–60 percent solids in a vacuum evaporator before homogenization and drying. Most drying is done using a spray-dryer where the concentrated viscous whey is passed through an atomizer and allowed to fall through a chamber with countercurrent heated air to produce a dispersible and nonhygroscopic powder of around 10 percent moisture. Spray-dryers can produce as much as twenty metric tons per hour of powder. Further processing can take place on a fluidized bed dryer where heated air is passed up through a vibrating layer of powder to further reduce the moisture to around 4 percent. A lecithin mixture can also be sprayed onto the powder to promote dissolution in water, a procedure known as instantization. Other types of dryers that are less commonly used include drum and roller dryers and freeze dryers. Roller dryers result in a much more irregularly shaped powder particle than spray-dryers.

Typical composition of whey powder is shown in Table 1. These powders are called whey protein concentrates (WPC), and suffixed with a number to indicate the percentage of protein, for example, WPC 80 contains 80 percent protein. Generally, the higher the protein content, the higher the price that the powder commands in the market. The solubility of powders can be enhanced

by collecting the smallest particles in a spray-dryer cyclone and mixing back with the partially dried powder at the top of the dryer. This creates an agglomerated particle with a surface containing many crevices, thus increasing the total surface area of a particle and increasing the solubility.

Higher protein levels in excess of 90 percent can be achieved by a combination of ion-exchange chromatography, electrodialysis to remove minerals, evaporation, ultrafiltration, lactose crystallization, and filtration. Whey protein isolates (WPI) are produced by ion-exchange and have a typical protein content of 93 percent. These isolates command a higher market price than WPC powders. The amount of fat in WPI is much lower than WPC, at around 0.5 percent. Ingredient applications for WPC and WPI include fortifying beverages such as high energy sports drinks, infant formulas, salad dressings, ice cream, custards, reformed meats, yogurt, surimi, bakery, and dessert products (as an egg replacement).

Lactose in milk powder is in the form of a concentrated amorphous (non-crystalline) glass that is very hygroscopic (high propensity for absorbing water). Milk powders that are high in lactose can potentially aggregate and lose the ability to flow freely. To avoid this problem, concentrated liquid whey is held at refrigeration

temperatures for twenty-four hours prior to drying to ensure that lactose crystallizes into the stable and non-hygroscopic  $\alpha$ -hydrate polymorph to reduce the propensity for powder caking. The concentrated whey is injected into the spray-dryer at less than 126°F (52°C) to prevent solubilization of the  $\alpha$ -hydrate crystals.

Lactose can be converted to galactose and glucose by the enzyme lactase. This procedure can be utilized to manufacture a low-lactose whey powder, which is sweeter, but more likely to undergo Maillard browning reactions than regular whey powder. Lactase can also be encapsulated and added to milk. Once the milk is consumed, the capsules break open, releasing the lactase, thus preventing the occurrence of lactose-intolerance symptoms.

The degree of heat-treatment of milk powders is quantified by the whey protein nitrogen index (WPNI), a measure of the quantity of whey proteins that are not denatured. Excessive heat during spray-drying causes a large degree of protein denaturation with subsequent loss of solubility of the powder. Low heat powder has a WPNI greater than 6 milligrams of nitrogen per gram, medium heat between 1.5 and 6 milligrams of nitrogen per gram, and high heat less than 1.5 milligrams of nitrogen per gram of powder. The degree of heating of powder during manufacture has implications for solubility, heat stability, viscosity, and flavor of the dairy product containing whey powder. High-heat powder will give high viscosity when added to yogurt, good heat stability in reconstituted evaporated milk, and intense flavor when used in milk chocolate, but poor clotting properties for recombined milk used in cheese manufacture.

### Buttermilk Powder

Buttermilk contains many surface-active components that function as emulsifiers. By making changes to the butter manufacturing process, different kinds of buttermilk powder (BMP) can be produced with various functional properties when used as a food ingredient. There is some scientific evidence that the components of the milk fat globule membrane layer are essential for development of cheese flavor during the ripening period. If this is so, BMP could find a use in fortifying low fat cheese to improve the flavor. Other applications for BMP include emulsifying fat in salad dressing, bakery products, ice cream, dips, and spreads.

The composition of BMP is not as tightly controlled as for other milk powders, as it is often thought of as a secondary product coming out of the primary process of butter manufacture. Volumes produced of this powder are generally much lower than for other powders, so their full potential has not yet been fully explored. BMP comprises mostly lactose with around 10 percent fat. About one-fifth of the fat comprises phospholipids, the highly surface-active components that are used as emulsifiers.

### Casein and Caseinate Powders

Casein powder is produced by isoelectric precipitation of milk using mineral acids, lactic acid bacteria fermentation, or enzymatic coagulation by chymosin (rennet). New Zealand is the world's largest producer of casein powder. A combination of acid and chymosin is used to prepare a low-viscosity casein for use in the paper industry to bind pigments. Precipitated casein curds are washed in water to remove residual lactose, whey proteins, and minerals, then pressed with rollers, dried (using a fluid bed dryer), and ground into a powder. Attrition drying occurs when casein curd is ground and dried by exposure to hot air concurrently. These particles are highly irregular in shape and more soluble in water.

Applications of casein powder include paper coating, adhesives, water-based paints, food ingredients, and animal feed. Food ingredient applications include beer and wine clarification, protein fortification of food, and texturized simulated meat products. Casein hydrolyzates are formed by partial acid hydrolysis of casein to improve the flavor of soups, dried meat products, crackers, and snack foods.

Caseinate is produced from acid casein by increasing the pH toward neutrality to dissolve the precipitated casein. Most commonly, sodium and calcium hydroxides are used to prepare sodium and calcium caseinate, respectively. Caseinates can be spray-dried after reconstituting in water to around 20–25 percent total solid material. The ingredient application for dried caseinates includes sausages, coffee whitener, ice cream and dairy-based desserts, soups, crackers, and sauces.

### Other Milk Powders

Other types of milk powder include skim milk powder (SMP), whole milk powder (WMP), cream powder, lactalbumin, colostrum, cheese powder, and milk protein concentrate. WMP contains around 30 percent fat, whereas SMP contains less than 1.5 percent. Lactalbumin powder is formed by heat-induced precipitation of cheese whey followed by drying. This powder is insoluble in water.

Cheese powder is produced from highly flavored cheeses such as cheddar and parmesan, by grinding, adding water and emulsifying salts to form a viscous suspension, followed by pasteurization, homogenization, and spray drying. This product quickly deteriorates after several months. The major ingredient application is for use as a cheese flavoring in food products.

Cream can also be spray dried to form a high fat (40–75 percent) powder. The amount of free fat in milk powders is of importance and affects dispersibility in water. This free fat is usually located on the surface and within crevices on the powder particle.

Co-precipitates are produced by heating skim milk to 185°F (85°C), whereupon the whey proteins denature and bind to the casein micelles. This complex is precip-

itated by acid and processed to a powder using the same procedure as casein powder production.

Milk is an important food from a nutritional perspective, largely due to the presence of proteins and calcium. The high water content and only slightly acidic pH render this food susceptible to microbiological spoilage. The dairy processing industry has developed to circumvent the spoilage issue through production of products with low moisture and higher acidity. This allows the development of a dairy products export market, as milk products can now be shipped to distant lands without compromising quality and safety. The huge variety of dairy products, most notably illustrated by the seemingly unending array of cheeses, is a testimony to the potential of milk for continued development of nutritious and tasty milk-based foods.

David W. Everett

**DAY OF THE DEAD.** In Mexico, the festival of Día de los Muertos embodies the greatest expression of both popular Catholicism and the national cuisine. People construct altars in homes and graveyards throughout the country in order to feed the souls of the dead. Church

officials recognize two holy days, November 1 (All Saints' Day), in commemoration of saints and martyrs, and November 2 (All Souls' Day), in memory of the faithful departed. According to popular belief, the *angelitos* (deceased children) return on the evening of October 31 and the adults on the following night, although the dates in local celebrations vary all the way from October 28 to November 4. The feast for the dead originated as a form of ancestor worship, and the clergy were long reluctant to incorporate such pagan practices into the liturgical calendar. The festival held particularly strong associations with pre-Hispanic agrarian cults because it coincided with the maize harvest.

Celebrations begin with the cleaning of the graves and the construction of the *ofrenda*, or altar. At home this consists of a table or platform hung from the ceiling, covered with a white cloth and supporting an arch of palm fronds. The *ofrenda* are decorated with flowers, particularly the *cempasúchil* (marigold), the "flower of the dead," as well as the magenta-colored cockscomb, a white gypsophila, gladioli, and carnations. The same flowers are also used to decorate tombs, and the sweet smell of copal, the Native American incense, is ubiquitous. Other altar decorations include images of the deceased as well as *papeles picados*, colored paper with cutout designs.

The foods offered to the dead vary according to age and taste, but bread, water, and salt are always included. The bread is made from a special egg dough in a round shape, with crisscrossed strips of dough forming bones, and a skull in the center. Sugar candies with similar skull and *calavera* (skeleton) designs are also popular. In some areas of Oaxaca and Michoacán, bakers shape the bread to resemble humans or animals. Offerings for children are miniature in size and relatively simple: breads, candies, fruits, and milk or soft drinks. The adult dead receive the finest foods, grown-up breads and sugar figures, as well as candied pumpkin and other sweets. More elab-

orate preparations include mole (turkey in a rich chili sauce) and tamales (corn dumplings stuffed with meat and chili and steamed in husks or banana leaves). The spirits also drink their favorite beverages, whether soft drinks, coffee, chocolate, beer, or tequila. Some people maintain that the level of the liquid decreases overnight, showing that the dead do indeed return to share in the feast.

The Day of the Dead has recently become an important tourist attraction for towns such as Mixquic, near Mexico City, and in the state of Oaxaca. Yet despite this increasing commercialization, the festival exemplifies the distinctiveness of the Mexican mentality; rather than a time of trick or treat, it celebrates the intimate connections between the living and the dead.

**DEATH AND BURIAL.** As far back as records go, we have evidence of the dead being laid to rest with care and ritual. Burial gifts, including food vessels and household utensils from different eras, have been discovered in archaeological remains in various parts of the world. These gifts are thought to have been intended for the use of the deceased on his or her journey to paradise or the land of the dead and to secure entry and acceptance in the new abode. Even those who suffered violent death were buried in specific ways, and it is of interest to note that two young men who appear to have been ritually sacrificed during the European Iron Age had consumed a meal before being killed. The so-called "Tollund Man," buried in a Danish bog about 500 B.C.E., had eaten a meal of porridge of some kind, and the "Lindow Man," buried in a peat bog at Lindow Moss, Cheshire, England, sometime during the fourth century B.C.E., had consumed "a

kind of wholemeal bread consisting of different kinds of grains,” just prior to his violent death (Green, 1992, pp. 132 and 210–111).

Although the Christian churches have, for centuries, regulated the liturgy and ceremonies for the dying and the dead, people everywhere have created their own death rites and have often retained them in addition to those of the official Church. Food and drink are often important elements of these rites, and they are sometimes associated with the dying state. In Ireland, for example, as Patricia Lysaght has shown, the dying were thought to suffer from hunger and thirst at death, and thus a dying person's request for food and drink always had to be granted. This food, served in anticipation of death, was termed *lón báis* (death sustenance); it was thought to be necessary to enable the person to die and thus to enter upon the journey to the land of the dead (Lysaght, 1995, p. 32). In many cultures this journey was said to be long and hazardous, and sustenance, provided by the living, was considered necessary. Food and drink were, therefore, served at various junctures during the wake and funeral, so that, as Greek tradition expresses it, “the dead may eat” (Danforth, 1982, Plate 22).

These foodstuffs were often left specifically in the presence of the deceased or placed in the coffin, or put into or placed on the grave. Formerly, in parts of Britain, bread and beer, or salt and bread, were consumed by a so-called “sin-eater” in the presence of the deceased; this person was thought to take on the sins of the deceased and thus enable him or her to be incorporated into the Christian otherworld (Hole, 1953, pp. 224–225; Kvide-land, 1993).

Food and drink consumed by the living during the wake and at the post-funeral meal were evidently also thought to provide necessary nourishment for the deceased, and thus to facilitate the transfer to the other world. Such food and drink have also been looked upon as a means of strengthening family and community in the face of death.

Food and drink also featured in ceremonies for the dead held at intervals varying from thirty or forty days after death in some societies, to three years among the Skolt Lapps of northern Europe when the dead person's final incorporation among the confraternity of the dead was thought to take place (Storå, 1971, p. 272), to several years in cultures where secondary burial was customary. At Christmas, Easter, and Whitsuntide (or Pentecost), the family dead were remembered by, among other things, gifts of food and drink. On November 2, the Feast of All Souls, prayers were recited throughout much of Catholic Europe for the souls of the dead. In addition, food and drink were placed on graves or left ready in the family home for deceased members, particularly the suffering souls in purgatory, who, according to an ancient and widespread popular belief, were thought to congregate there from midnight until cockcrow.

## FOOD AND THE SIN-EATER

Sin-eating as a funeral custom was once common in parts of England, Scotland, and Wales. It is mentioned in records from the seventeenth to the nineteenth century. For a trifling payment, a man or woman of the locality known as a sin-eater was believed to take upon him or herself, by eating and drinking, the sins of the deceased. According to John Aubrey, writing in 1686–1687 (Aubrey, 1972, p. 179) and referring to the County of Hereford in England, the rite was performed when the deceased was being removed from the house for burial. The corpse was placed on a bier before the door, and a loaf of bread and a bowl of beer were passed over the deceased to the sin-eater, who consumed them and was given a sixpence as payment. The sin-eater was thus thought to assume the sins of the deceased and thereby bring ease and rest to the departed soul.

What is probably an older form of the custom is mentioned for western Scotland in 1879. Here the sin-eater was taken into the corpse-room where he was said to have consumed a plate of salt and a plate of bread placed on the breast of the corpse, and thus to have eaten his sins (Napier, 1879, 60–61).

The custom of sin-eating is apparently older than the seventeenth century and is said to derive from the scapegoat in Leviticus 16: 21, 22. What might be regarded as a symbolic survival of the custom in parts of Europe was the passing of drink and a funeral biscuit over the corpse, or the placing of a funeral cake on the breast of the deceased for consumption by the nearest relative, or, indeed, the placing of salt on the breast of the deceased as was common, for example, in Ireland. The “death cakes” introduced into America from Europe in the seventeenth century and served to guests at a funeral and the “burial cakes” still made in parts of rural England in the early twentieth century might well reflect the custom of sin-eating.

## Kinds of Drink and Food

Alcoholic beverages were a feature of wake and funeral hospitality throughout much of Europe until relatively recent times (Ó Súilleabháin, 1967, pp. 154–157). In Latvia, for example, the expression *dzert bīres*, ‘to drink a funeral’, is testimony to this (Dumpe, 2002, p. 125). The apparently liberal provision of alcohol at wakes and funerals in Ireland was repeatedly condemned by secular and ecclesiastical commentators from the seventeenth to the twentieth century. Occasional references to elaborate funeral meals that included beer, wine, beef, and wheaten

Philadelphia funeral biscuit mold from about 1785 depicting the plumes that decorated the corners of the hearse and were also worn by the horses pulling it. There were bakers in most East Coast cities who specialized in funeral biscuits and in catering funerals. ROUGHWOOD COLLECTION.

bread occur in seventeenth- and eighteenth-century literature, but by the late nineteenth century, the wakefoods commonly mentioned include shop-bought goods, especially white bread, fruit cake, jam, and tea, and alcoholic beverages in modest quantities. Today, where wakes survive, food (sandwiches, cake, tea, coffee), and alcoholic beverages (wine, beer, Guinness, spirits) are served, but the most significant funeral repast in rural and urban Ireland today is generally the postburial meal in the mourning home or in a restaurant (Lysaght, 2002).

In eighteenth-century Scotland, England, and the Isle of Man, food and alcohol were liberally provided at wakes and funerals by people of rank (Bennett, pp. 207–211; Hole, pp. 228–229 and 233; Moore, p. 160). More typical, at least for Scotland, in recent times, was the provision of cheese and oatcakes, sometimes shortbread, served with ale or tea, and spirits, to which could be added wine and biscuits. The corpse-watchers received whisky (and pipes and tobacco), and often tea, or bread and cheese with ale, about midnight. Funeral guests were similarly treated. If the cemetery was some distance away, whisky was sometimes served at a particular spot en route, and again in the cemetery after burial. In parts of northern Scotland a meal called a *dredgy* was served in the deceased's home after the burial (Fenton, 2002, pp. 212–213).

In Portugal, as shown by Mouette Barboff, grain, bread, and wine have played significant roles in death customs. Lamenting women were paid in rye and wheat, while water, millet-bread soaked in wine, and a coin were placed in the deceased's coffin, for the journey to the otherworld. In the north, where death customs remain particularly strong, funeral bread is distributed at the church and cemetery. In the Beira region, two cornbread loaves, divided into eight pieces, are given to the poor on removal of the coffin from the house, while in the Barroso,

rye loaves (*o carolo*) are distributed on leaving the church. In the Minho, a slice of cornbread with a piece of fish (sardine or cod), or wheaten bread (*molete*), is distributed to all funeral guests. The priest is given bread, wine, or grain, and perhaps fish or meat. Nowadays, the tendency is to pay the priest in cash. On the first anniversary of the death, thirty or forty loaves of bread called *pão da caridade* (charity bread) or *pão das almas* (soul bread), baked by the family, are distributed to the poor of the parish in return for prayers for the deceased. On the Feast of All Souls (November 2), children call to houses asking for the *pão por Deus* (God's bread) for the holy souls (Barboff, 2002, pp. 204–206).

Elsewhere in Europe, the provision of food and drink on the occasion of death has also been highly structured. In Westphalia in northern Germany, it is still customary to provide *Beerdigungskaffee* (funeral coffee), with plain or sugar biscuits (*Zwieback/Zuckerzwieback*), pastries, and open sandwiches (*belegtes Brötchen*) for the funeral participants in a local hostelry after the burial. As late as the 1960s, a very elaborate meal (*Leichenmahl*) consisting of, for example, *bouillon*, a large meat platter with roast sausage, pork, and fowl, served with potatoes, red cabbage, and applesauce, followed by a pudding dessert, cigars for the menfolk, and afternoon coffee with pastries and sandwiches, might still be provided in well-to-do farmhouses for the relatives and near neighbors of the deceased.

In parts of Lower Austria in the 1970s, food and drink were served at certain junctures during the wake for the dead. On completion of the rosary, bread, wine, and fruit such as apples, dried prunes, and pears were provided. After the singing of funeral songs, more food and drink, which could include coffee and the much-

A funeral biscuit made from the circa 1785 mold. Reconstructed recipe and icing technique by William Woys Weaver. ROUGHWOOD COLLECTION.

An Irish wake, complete with wailing relatives and a spread of whisky on the table to the far right. An engraving from Mr. and Mrs. Samuel Carter Hall's *Ireland. Its Scenery, Character &c.* (London, 1841). PUBLISHED WITH PERMISSION OF THE FOLKLORE SOCIETY, LONDON.

appreciated crumbled bread soaked in coffee and eaten with a spoon, were served. Schnapps was provided in most areas, followed sometimes by black bread but mostly by white *Totenbrot* (funeral bread), with wine or beer. Much alcohol was drunk. Meat was only seldom offered.

Early on the morning of the funeral, relatives, friends, neighbors, and the coffin bearers were invited to the funeral breakfast, consisting mostly of coffee and white bread, although a nutritious meal with a substantial fat content was sometimes served to the coffin bearers. Schnapps and wine were also provided.

The funeral meal (*Leichenmahl*), to which relatives, neighbors, helpers, the priest, and mass servers were invited, was held either at an inn or in the mourning house. It could be very elaborate, consisting of several courses and including various kinds of bread and cheese, and, in certain areas, wine or beer (Huber, 1981, pp. 74–147).

In eastern Europe, festive food and drink were also associated with death in Slovakia. A slice of bread and a small glass of brandy were placed in the room for the soul of the deceased. Bread was placed in the coffin or grave or given to beggars or gravediggers in payment for prayers for the deceased. In the mountain regions, bread, salt, curds or cheese, and brandy were served. A cock was killed for the death of a farmer and a hen for that of his wife. A weddinglike feast was held for an unmarried deceased, especially a young man or woman (Stoličná, p. 118). A similar practice formerly took place in Hungary (Viski, pp. 181–182) and elsewhere in Europe (cf. Fielhauer, 1970).

In parts of southern Europe, for example in Greece, food plays a very substantial role in the elaborate and extended funeral customs of Greek Orthodox tradition. (Danforth). At the burial, prior to the closing of the coffin in the grave, the priest pours a bottle of red wine in the form of a cross over the shrouded body of the deceased. *Koliva* (boiled wheat mixed with sugar and cinnamon and decorated with nuts and raisins) and bread are shared in the church courtyard by the funeral participants, who pray for the forgiveness of the deceased. None of this food is brought into the deceased's house, where the guests are offered water, cognac, cigarettes, and candy as they convey their condolences to the relatives. After coffee and biscuits have been served, the priest blesses *koliva*, wine, and bread (i.e., *makario*, "that which is blessed") and distributes them to the close relatives of the deceased (Danforth, 1982, pp. 42–43).

On the eve of the third day after death, *koliva*, bread, candy, and pastries are again distributed in the church courtyard after the memorial service at the grave, and guests again receive coffee, cognac, biscuits, and candy in the house of the deceased. These ceremonies may be repeated on the ninth day and six months after the death. Forty days after death, another memorial service is performed in the cemetery, after which a sweet wheaten pudding called *panbidha* is blessed by the priest and served to the guests in the church courtyard together with special funeral bread, pastries, honey, candy, and vermouth. Finally, guests are invited to the deceased's house for a very elaborate meal that includes meat, indicating that

the relatives—who have abstained from meat for forty days—are being reincorporated into the normal life of the community (Danforth, 1982, pp. 43–44).

On occasions of collective commemoration of the dead, called *Psihosavato* (Soul Saturdays or All Souls' Days), offerings of *koliva*, bread, cheese, olives, and fruit are brought by women in rural Greece to the village church. There they are blessed by the priest, who also recites the names of the village dead. The food offerings brought by the women individually in honor of their own dead are then distributed to the others present in honor of all the dead (Danforth, 1982, p. 56).

The rite of exhumation, in which food and drink also feature, is normally performed after five years, at which stage the deceased is thought to have reached his or her final resting place. The priest pours a bottle of red wine over the bones, making the sign of the cross three times with the liquid. Those present are offered "a small glass of sweet red wine," *koliva*, "a slice of bread, a spoonful of honey, and several pastries, sweets, and other candies," by distant relatives and friends of the family. On returning to the family's house, they are "offered water, cognac, and candy" and later "coffee, small biscuits, and pastries," after which they compliment the family in a traditional manner for the reception provided (Danforth, 1982, p. 21).

Many Old World death customs, including the provision of refreshments at wakes and funerals, traveled to the New World with emigrant groups. William Woys Weaver shows that in colonial America, the provision of lavish funeral hospitality, either in the deceased's home or in a local hostelry, was well established by the late eighteenth century. Among the foods served by the Pennsylvania Dutch was a rich fruit cake, but funeral biscuits were also common. Some varieties, like the Dutch *dood-koecks* (death cakes), bore the initials of the deceased and were given to mourners in old New York. Others featured highly symbolic motifs such as a rooster, a heart, "a cherub or winged head . . . an hourglass, or even a skull" (Weaver, pp. 107–108). As in the Yorkshire Dales and Lincolnshire in England, the biscuits were flavored with caraway or tansy seeds (Weaver, p. 108). In Montgomery County, Pennsylvania, "funeral bread" (bread "sweetened with sugar or honey and containing caraway seeds or dried fruit"), funeral biscuits, and wine were served to the guests as they left the church on their way to the cemetery (Weaver, 1989, p. 110).

Commemoration of the dead during the feasts of All Saints and All Souls (November 1 and 2) is an especially exuberant affair in Mexican Catholic tradition. During the festival of *Todos Santos* (All Saints), or *Día* or *Días de Muertos* (Day or Days of the Dead), extending from the eve of October 30 to the evening of November 2, offerings of food and drink are made to the dead by being placed on the "dressed" graves and on the very elaborate altars for the dead that are prepared in the family home (Carmichael and Sayer, 1991, pp. 14–21).

In the New World, therefore, as in the Old, the provision of food and drink at wakes and funerals was an important act of *pietas* and effectively a social obligation. Thus, their provision was highly regulated and a matter of strict observance in many different societies.

**DELMONICO FAMILY.** The Delmonicos are a family dynasty of restaurateurs of Italian Swiss origin who created some of the most legendary and opulent restaurants in the United States.

The principal founders of the American clan were the brothers Pietro Antonio (1783–1861) and Giovanni (1788–1842) Del Monico, who established themselves under the names Peter and John Delmonico at 23 William Street in New York in 1827. Shrewdly advertising their business as a European-style café in New York's business district, the brothers quickly amassed a fortune based on excellent service and a menu that became a magnet for New York's European expatriates and American nouveaux riches.

As the business grew and thrived, other members of the family emigrated from Switzerland and joined Peter and John, including a nephew Lorenzo (1813–1881) who eventually became the genius behind the success of the family's restaurant empire. Lorenzo joined the firm in 1831 when it expanded from a café into a true *restaurant française*. This first restaurant, at 25 William Street, was only the first of several locations that eventually opened and operated under the Delmonico name. As businesses moved uptown, Delmonico's followed. In 1876, Lorenzo moved the main restaurant to Fifth Avenue and Twenty-sixth Street, facing Madison Square. This new address, complete with a ballroom that quickly became the centerpiece of New York society, launched Delmonico's into

A private dinner at Delmonico's Forty-fourth Street restaurant in 1898. © BETTMAN/CORBIS.

New York's Gilded Age and perhaps the restaurant's greatest period of fame.

Under the oversight of European-trained chef Charles Ranhofer, Delmonico became synonymous with ostentatious banquets and gastronomic sensations. Ranhofer's encyclopedic cookbook called *The Epicurean* (1894) records many of the recipes and menus that made Delmonico's famous during his culinary reign. *The Delmonico Cookbook* (1880), a less opulent cookbook by former Delmonico chef Alessandro Filippini, also records many of the foods served in the restaurant. Throughout much of the history of the various restaurants owned by the family, the majority of customers were businessmen; women were not served in the public dining rooms unless escorted, although this rule was relaxed somewhat during the 1880s. The famous dinners at which women were present were held in ornately furnished private rooms designed for this purpose.

The restaurant's last move occurred in 1897 when it took up a new location on Fifth Avenue at Forty-fourth Street. The Delmonico restaurant empire eventually became overextended and difficult to manage. The business closed its doors in 1923, a victim of income tax, Prohibition, and changing lifestyles of New York's rich and famous. Today the name Delmonico survives in a pudding, a melon, and a cut of steak taken from a rib of beef, the American equivalent of *entrecôte*.

**DENTISTRY.** Food and dental health interact, with each having effects on the other. Patterns of eating affect the health of the teeth and other tissues in the mouth, while the ability to chew a variety of foods without discomfort influences a person's nutritional state as well as his or her enjoyment of eating.

#### Sugar and Dental Caries

The clearest link between food and dental health is between sugar consumption and caries (cavities). A study in the 1940s compared the dental health of children in an area of northern India, where food was scarce and malnutrition common, to that of better-nourished children in Lahore and in Rochester, New York. The poorly nour-

ished children had the fewest cavities. Subsequent research confirmed that populations who enjoyed a good nutritional status had more caries than less well-nourished populations.

Researchers then looked at the mechanism of caries development to discern the role of diet. Cavities are the end result of a process that involves bacteria and sugars in the mouth over time. *Streptococcus mutans*, bacteria that are normally present in plaque, a very fine film which covers the surfaces of the teeth, metabolize sugar and form acid. When a person consumes sugar in foods or beverages, acid is formed that can dissolve minute amounts of minerals from the enamel surface of the tooth. When this happens repeatedly over time, enough minerals are lost for a cavity to form.

This relationship between sugar consumption and caries was tested in a classic study conducted at Vipeholm, a mental institution in Sweden, and reported in 1954. Although modern ethical standards would preclude a study in which subjects were unable to give informed consent, it remains a landmark piece of research. Residents were assigned to several groups. All ate the standard diet of the institution, but some were given additional sweets in varying quantities and frequency, up to twenty-four sticky toffee candies per day. After five years of observation, the researchers concluded that the stickiness of the sweets and the frequency with which they were consumed, both increasing the amount of time that the bacteria in plaque could produce acid, were more important than the total amount of sugar.

*Streptococcus mutans* can feed on any carbohydrate, not just sugars. The bacteria make no distinction between "natural" carbohydrates, such as the sugars in fruit, and refined sugars; they make acid from any of them.

Oral bacteria also make acid from sugar in liquids. This can lead to a particular pattern of caries called "baby-bottle caries," which develops when a baby is put to bed with a bottle filled with sugar-containing liquid, including milk. When the baby falls asleep, the liquid pools in the mouth, leading to decay, most often of the front upper teeth.

Since sugar has been shown to play such a significant role in the development of tooth decay, a basic preventive measure is to limit the frequency of sugar consumption. Because it is the action of bacteria on the sugar that is of concern, minimizing the bacteria by careful attention to oral hygiene is equally important. Fluoride, a mineral that is naturally present in water in some areas, has a strong protective effect as well. It binds to the other minerals to become part of the enamel, making the enamel harder and more resistant to decay. It also slows acid formation and promotes repair of places on the teeth where acid has dissolved some of the minerals.

In areas where the naturally occurring level of fluoride in water is low, it is often added during water treatment. Although there have been controversies about

water fluoridation, public health authorities, including the American Dental Association, the United States Public Health Service, and the World Health Organization, all support it as a safe and effective preventive measure. One can see its effectiveness in the fact that, although sugar consumption in the United States has been increasing, children have fewer cavities than they had in the years before fluoridation became widespread.

Sugar substitutes are used to produce candies, chewing gum, and beverages that taste sweet without harming the teeth. Chewing gum containing xylitol, one of these alternative sweeteners, has been shown to be protective.

### Diet and Periodontal Disease

Gingivitis, or periodontal disease, is the other common dental disorder. The bacteria in dental plaque cause an infection of the gums and structures that hold the teeth in place. The gums become red, swollen, and tender. Food does not play an important role in the development of gum disease, as it does in the formation of caries. Good oral hygiene is the most important preventive measure. A nutritious diet, which supplies generous amounts of vitamins and minerals, can offer some benefit by helping to maintain the immune system's ability to fight the infection.

### Dental Status and Eating

The other side of the food and dental health interaction is the importance of healthy dentition in enabling people to eat and enjoy a wide variety of foods. The absence of a significant number of teeth or a condition such as periodontal disease or poorly fitting dentures, which makes chewing uncomfortable, may limit a person's food choices and compromise his or her nutritional status. This problem occurs most frequently in elderly and low-income populations, who are more likely to be at risk for nutritional problems.

Some researchers do not find this effect, possibly because the subjects with poor dentition have chosen nutritious foods that are easy to chew, or because the comparison population ate no better in spite of good dental status. In general, however, poor dental health increases the risk of poor nutritional health. Good dental care can correct most of these problems and enable individuals to enjoy eating a nutritious diet.

**DIASPORA.** The term "diaspora" was first used to describe the shared experience of the Jewish peoples—experience of exile and displacement, but also of continuing (some would say strengthening) connection and identification. Etymologically, "diaspora" derives from Greek *dia* ('through') and *speirein* ('to sow, scatter'). The word is used more broadly to refer to the cultural connections maintained by a group of people who have been dispersed or who have migrated around the globe. Each distinct "diasporic group" or "community" is a composite of many journeys to different parts of the world, occurring over very different timescales. The experiences of particular subgroups can therefore vary considerably—to the extent that some writers argue it is meaningless to talk of shared identities and experiences of, for example, "the South Asian diaspora," at the global level. Avtar Brah's book *Cartographies of Diaspora* provides a detailed discussion of the complex history and uses of the concept.

A key characteristic of diasporas is that a strong sense of connection to a homeland is maintained through cultural practices and ways of life. As Brah reminds us, this "homeland" might be imaginary rather than real, and its existence need not be tied to any desire to "return" home. The maintenance of these kinds of cultural connections can in some cases provoke both nostalgic and separatist tendencies. The focus here is on the place of cooking and eating among the enduring habits, rituals, and everyday practices that are collectively used to sustain a shared sense of diasporic cultural identity, in recognition that culinary culture has an important part to play in diasporic identifications.

### Diasporic Foodscapes

Among the everyday cultural practices routinely used to maintain (and in some cases enhance or even reinvent) diasporic identities, food is commonly of central importance. There are a number of reasons for this. First, food traditions and habits are comparatively portable: groups that migrate around the world often carry with them elements of the diet and eating habits of the "homeland." Indeed, the migrations of foods can be used to track the past movements of people, a cornerstone of research into

foodways and foodscapes. Every nation's diet therefore bears the imprint of countless past immigrations. Second, foodways are adaptable: While migrations can map the movements of ingredients, foodstuffs, or methods of preparation into new habitats unchanged, they also tell tales of adaptation, substitution, and indigenization. As people and their cuisines move, they also change to suit local conditions. Ghassan Hage's research with Lebanese migrants in Australia provides a simple illustration. In his essay "At Home in the Entrails of the West," based on interviews with Lebanese migrants to the Parramatta area of Sydney, Hage reports on this process of adaptation and substitution. One of his respondents talks about using peanut butter in Lebanese dishes in place of tahini, which was not at the time available in Australia. (In fact, when tahini later became available, the respondent admits to craving peanut butter.) Over time, this reshaping of ingredients and cooking methods often leads to a reshaping of diasporic culinary cultures, such that the dishes sometimes bear little resemblance to the original version. Comparing the same dishes among diasporic groups in different countries (say, the Chinese in the United States and in the United Kingdom) makes this clear, as does comparing diasporic versions of dishes with those served "back home."

This mobility and adaptability assures that food habits are usually maintained (even while they are transformed) among diasporic groups. Occasionally entire culinary cultures may be preserved. More often, "traditional" foods are maintained only in particular symbolic meals or dishes. For example, the small community of Russian Molokans in the United States perpetuates the rituals of preparing and sharing formal community dinners, or *obedy* (as reported by Willard B. Moore in "Metaphor and Changing Reality"). Alternatively, a particular dish can be singled out as embodying and preserving diasporic identity, as in the case of the *ghormeh-sabzi*, a stew eaten by Iranian immigrants in central England. This dish has particular significance as a way to reconnect with Iranian culture, tradition, and beliefs. A detailed discussion of the place of *ghormeh-sabzi* can be found in Lynn Harbottle's essay, "'Bastard' Chicken or *Ghormeh-sabzi*?" Harbottle's respondents report that they had to make compromises in their families' diets, allowing some Western dishes onto the table, even though they were generally wary of losing their cultural identity through Westernization. However, they expressed health concerns about the inferiority of the food in England compared with their diet back in Iran, and were keen to maintain the cultural and religious significance of food habits and pass them on to future generations. (These habits were mainly connected with their Shi'ite faith and the consumption of *halal* ingredients in accordance with Islamic dietary law.) In some cases, this led to the transformation of some staples of contemporary English cuisine, such as pizza or burgers, to realign them with Shi'ite

custom. The diasporic transformation of diet is, therefore, a two-way process.

In fact, the arrival of diasporic foodways can more broadly transform the "host culture" into which migrants move. In Britain, for example, the migration of South Asian peoples has brought with it a variety of "immigrant" cuisines. While these were maintained initially for the migrant communities as a reminder of "home," their popularity among non-Asian Britons is longstanding and has continued to grow. Certain indigenized dishes, such as chicken *tikka massala*, are among the most enthusiastically and widely eaten meals in Britain today. (This, of course, need not signal comfortable race relations away from the table; see Uma Narayan's essay on Indian food in the West, "Eating Cultures.")

### Diasporic Dilemmas

It would be wrong to simply equate the popularity of chicken *tikka massala* in Britain with the comfortable accommodation of South Asian migrants into a commonly shared and widely adopted multicultural identity. This is one of Hage's main points: the adoption of diasporic cuisines by host cultures often does little to encourage other forms of productive encounter between different ethnic groups. In fact, for Hage, the availability of diasporic foodstuffs permits a lazy "cosmo-multiculturalism," in which eating foreign dishes substitutes for other forms of engagement. Moreover, the necessity of maintaining "exotic" foodways can produce a distinct diasporic burden, fixing migrant culinary cultures rather than allowing them to change. There is, therefore, a set of ethical questions attached to the existence of diasporic foodscapes: For whom are they produced? What are their outcomes and effects? What alternatives might be suggested?

Two discussions can serve as illustrations of this dilemma. The first focuses on the role of the *döner kebap* among Turkish "economic migrants" in Germany. In his essay "McDöner," Ayse Caglar traces the ways in which the symbolic meaning of the *döner* has shifted over time. He notes its immense popularity in Germany, and reminds us that the dish was invented for non-Turkish Germans and does not exist in Turkey in the form it is now served—as a fast food consisting of meat slices in *pide* (Turkish flatbread), garnished with salad and sauces, bought on the street from an *Imbiss* (mobile stand). Moreover, the vast majority of *döners* are eaten by non-Turkish Germans. Back in the 1960s, *döner* vendors traded heavily on the ethnic exoticness or Turkishness of the *döner*, but since the early 1990s the food has been increasingly deracialized, shedding its ethnic signifiers and in many cases being rebranded using American symbols—hence the "McDöner" of Caglar's title. This shift, Caglar explains, mirrored the mounting social marginalization of Turks in Germany.

In the case of the *döner kebab*, then, we can witness the “invention” of a food symbolic of ethnic identity, though in this case (unlike the Iranian *ghormeh-sabzi*) the food is largely consumed by the “host culture” rather than by the immigrants. The “ethnic” markers attached to the *döner* have subsequently been shed, reflecting the shifting social position of the migrant group. As a final irony, Caglar notes that successful Turkish caterers in Germany have switched to serving Italian food to a more up-market clientele.

A second example is provided by David Parker, in an essay called “The Chinese Takeaway and the Diasporic Habitus.” Like the indigenized Indian curry house (a key provider of chicken *tikka massala*), the Chinese takeaway (takeout shop or restaurant) has come to occupy a particular symbolic location on the British culinary landscape. However, foods from the South and East Asian subcontinents are available through all kinds of other food outlets, from supermarkets to trendy eateries. Moreover, food is only one cultural product used in diasporic identifications; the development of distinct “ethnic quarters” such as Chinatowns in many cities testifies to a broader-based cultural infrastructure. For critics, the existence of such “ethnic quarters” merely furthers the economic exploitation of diaspora, while for other commentators it suggests the success of multiculturalism. Food outlets are commonly center stage in these kinds of urban areas, testifying to the significance of the food distribution as a site for diasporic cultural production.

Parker reads the Chinese takeaway as a key site for the negotiation of British Chineseness in relation to the global Chinese diaspora. By focusing on the encounters between workers and customers, Parker reveals a mode of interaction that he names the “diasporic habitus,” defined as “the embodied subjectivities poised between the legacies of the past, the imperatives of the present, and the possibilities of the future” (p. 75). This habitus shapes ways of “being Chinese” in diasporic contexts, and is the result of the uneven distribution of “imperial capital” between Chinese and non-Chinese Britons: what occurs in the takeaway bears the enduring imprint of colonial contact between Western and non-Western peoples. Parker shows not only how these encounters are overlaid by orientalist racialization, but also how this “contact zone” offers critical possibilities. Parker argues (like Hage) for a contested (instead of celebratory) multiculturalism that explores the complex interplay of identities in everyday locations. The takeaway, therefore, is an emblem of British Chineseness rather than Chineseness—a situational outcome of one particular diasporic foodscape.

Of course, the notion of British Chineseness still retains an emphasis on being (at least in part) Chinese, rather than simply British. This is part of the diasporic burden mentioned earlier: the necessity of retaining some degree of ethnic difference. In some cases, of course, migrant groups may wish to reject, either partially or wholly,

their ethnic identity, and adopt the identity of their new “home.” They may, however, be denied that possibility by the “host culture,” which wants to preserve their ethnic identity for a variety of reasons. The deracializing of *döner kebab* illustrates an attempt by German Turks to integrate more fully into German society at the same time that the ethnic marker of Turkishness was becoming increasingly problematic there.

The existence of diasporic cuisine marks a complex negotiation between cultural identities. For both German Turks and British Chinese, elements of their cuisines (or “invented” versions of them) have become institutionalized on the foodscape. While this may provide some level of economic security—the “success” of Chinese takeaways in Britain is often reported as evidence for multiculturalism, at least in terms of business culture—there are many compromises and dilemmas involved as well. As the *döner Imbiss* and the Chinese takeaway both illustrate, mundane yet intensely symbolic items such as food are woven in complex and shifting ways into discourses of tradition and transformation, identity, and community. Diasporic diets, like all aspects of diasporic identity and culture, are constantly remade, even while some key elements endure over time.

**DIETARY ASSESSMENT.** Dietary assessment is the process of evaluating what people eat by using one or several intake indicators. It is the best approach for identifying nutrients that are likely to either be under- or overconsumed by the individual or groups of interest. It also can be used to identify food patterns and preferences.

### **Dietary Status versus Nutritional Status**

Dietary status is related to but not necessarily reflective of nutritional status. Nutritional status is a more comprehensive term, referring to health status as it is affected by nutrition. It is measured not only by assessing dietary status, but also by anthropometric, biochemical, and clinical measures. Because dietary methods are less invasive, somewhat easier to obtain than other physiological measures, and do not require medical training, they often are used initially for assessing nutritional inadequacy or excess. Physiological measurements are then used to confirm and corroborate dietary intake evaluation and to arrive at definitive assessments of nutritional status.

### **Tools and Standards for Assessment**

To assess dietary intake, food composition tables for translating foods consumed into nutrients, and a reference against which dietary intakes may be compared, are needed. These tools have been updated and refined periodically and appropriate ways for applying them to assessment tasks are steadily clarified.

### **Overcoming Imperfections in Assessing Dietary Intake**

All dietary assessment methods are imperfect, regardless of how well they are designed. Their major shortcomings and measures for dealing with the imperfections are described briefly below.

### **Capture Actual Intakes**

The various methods for assessing dietary intake are summarized in Table 1 and elsewhere in detail (Dwyer, 1999). All assessment methods fail to capture actual energy intakes precisely and probably intakes of nutrients as well. Some of the errors are inevitable because human beings tend to misreport their food intakes, but the method used also influences assessment outcomes.

Dietary intake is sometimes assessed by an objective observer rather than by the eaters themselves. For example, the intake of a hospitalized patient often is assessed from measured differences of the food served to a patient less any unconsumed amounts. Such objective methods have the advantage of being less subject to reporting biases than those that rely solely on recall. However, more objective methods are time-consuming, costly, cannot usually be employed to assess typical intake, and fail to record all intake. Moreover, they may not reflect what people really eat, since people may eat differently when they know that they are being observed.

For these reasons, most commonly used dietary assessment methods rely on eaters' self-reported intakes.

Most methods such as twenty-four-hour recalls, food records, and diaries underreport actual energy intake by at least 20 percent. Underreporting errors are even higher (30 percent or more) in certain groups, such as the obese, women, and the elderly. However, they also vary among individuals in ways that are not always easily identified by demographic or other distinguishing characteristics. The causes of underreporting include forgetting, unconscious alterations in recalling foods eaten (for example, when the individual knows that he or she is being watched), attempts to please the questioner, and occasionally lack of cooperation by the subject. Non-random biases are difficult to deal with statistically.

Intakes obtained using semiquantitative food frequency questionnaires have other shortcomings. This method presents the respondent with a food list. These prompts may decrease forgetting, but insertions and "false memories" of foods consumed or of the consumption of socially desirable foods may be reported rather than true intakes. Semiquantitative food frequency questionnaires are too imprecise to estimate individual intakes quantitatively. Nutrient intakes from semiquantitative food frequency questionnaires usually are overestimated. They usually are adjusted statistically to obtain more accurate estimates of usual intakes. Measures of usual energy intakes for accurate groups specified by sex and age obtained by other methods or from estimates of energy outputs are used to adjust them. They are often derived by "food frequency" approaches and may be accurate enough to provide reasonable group estimates, although such measures are not sufficiently accurate for individuals. Also, precise quantification of absolute amounts (as opposed to levels of intake ranked into quartiles or quintiles) is not possible. The biases involved in food frequency questionnaires are complex, and statistical methods for obtaining valid estimates of intakes are unavailable.

Understandably, retrospective methods that rely on memory are subject to "forgetting bias." Prospective methods, which rely on reporting food intake immediately or shortly after eating, are more subject to alterations in intake due to the individual's awareness that his or her intake is being recorded. The extent to which social desirability and reporting biases intrude in the various methods is unknown, but is probably considerable.

Not all of the problems associated with misreporting can be overcome by the method of choice, but some can be minimized by selecting the appropriate tool for the task at hand.

### **Obtain Representative Intakes**

Dietary assessments must be done frequently and randomly to reflect usual intake faithfully. This is an important shortcoming because only usual intake is

TABLE 1

Dietary assessment methods	
Method	Description, advantages, and limitations of method
<b>Retrospective Methods</b>	
24-hour recall	Respondent recalls all foods and beverages consumed in a given 24-hour period and reports them to a trained interviewer, who probes to get additional details on portion sizes, frequency, and forgotten items. Positive aspects include low respondent burden, ease in administration, and minimization of biases associated with altering food intake because of knowledge that one is being observed. Negative aspects of the method include forgetting, deliberate misreporting, need for a trained observer to administer, need for several days of intakes to obtain estimate of usual diet, and costs associated with computerized analysis of records
Telephone recall	The respondent is contacted or instructed in advance and given instructions about estimating portion sizes and other details. Then the respondent is called by telephone and asked to report dietary intake over the past 24 hours. Probes and techniques are usually standardized to minimize reporting error. Positive aspects of the method include those listed above plus ability to obtain representative random days of intake, and decreased cost of administration. Negative aspects include inability to obtain interviews from those without telephones, and for those who find telephones difficult to use, and errors in reporting portion sizes.
Food frequency and semiquantitative food frequency questionnaire	Respondent chooses from a list of different foods or food groups usually eaten over the past month or year. The number and type of foods, and whether portion sizes are specified, varies from one questionnaire to another. Positive aspects of the method include ease of administration, low expense, less forgetting because of prompts furnished by food lists, somewhat more of an estimate of usual intake (perhaps equivalent to 2–3 days), and low costs of data analysis. Negative aspects of method include incomplete reporting of items not included in food lists, overreporting, incomplete or inaccurate response, inaccurate translation of food and food groups to nutrients, and imprecise estimates of nutrient intake
Dietary history	Respondent reports all foods and beverages consumed on a usual day to a trained interviewer. The interviewer then probes further on the frequency amount and portion size consumed. Diet diaries are sometimes used to assist respondents in recalling their intakes. Positive aspects of the method are that respondent burden is low and complete intakes are provided. Negatives include high cost, need for trained interviewers, and lack of standardization
<b>Prospective Methods</b>	
Weighed food record	After being instructed, respondent weighs all food and drink consumed on a small weighing scale and reports it on a record that is kept as close to the time of consumption as possible. If observers are available, they can carry out the weighing themselves. Positive aspects of the method are lack of forgetting bias, and ability to obtain random days of intake. Negatives include high respondent burden, refusal to record intakes, need for an expert observer to review and clarify intakes reported, tendency of respondents to alter food intake when they know they are under observation, and costs of data analysis.
Food diary	The respondent records all foods consumed in household measures, usually without measuring them, or only measuring foods that are particularly difficult to estimate. Positive aspects are same as food records but respondent burden is less. Negative aspects are that more errors in estimation of portion size may occur
Duplicate portion analysis	An observer takes duplicate portions of all foods consumed by the individual and weighs or measures them; in some cases, these may also be chemically analyzed. Positive aspects are similar to food records. Negative aspects are lack of respondent cooperation, need for trained observers, cost of food analysis, and inability to obtain estimate of usual intake.
<b>Other: Direct observation by trained observers or by videotaping subjects</b>	Observer records or watches food intake in a controlled or highly supervised environment in which it is possible to videotape or directly observe food intakes. Positive aspects of the methods are that they do not rely on respondent burden. Negative aspects are that the methods are usually too imprecise for obtaining valid estimates of individual intakes.

correlated with nutritional status. A representative sample of randomly chosen days that includes both weekdays and weekends is best for obtaining accurate twenty-four-hour recalls or records. Semiquantitative or other food frequency questionnaires also may assist in providing information on usual food intake patterns.

Obtain Total Intakes

Many foods and beverages are fortified with nutrients, and a substantial proportion of the population takes nutrient supplements on a regular basis. For some individ-

uals, these nutrient sources contribute a substantial amount of vitamins and minerals. Nutrient intakes from all sources, including foods and beverages, fortified foods, and nutrient supplements must be included in all dietary assessments. If only food sources are queried, this fact should be noted.

Use Complete Food Composition Tables

Once food intakes are obtained, these must be translated into nutrients using food, beverage, and supplement composition tables. Accurate nutrient intakes can be obtained

if up-to-date and complete food composition tables are available; that is, the composition of fortified foods, nutrient supplements, and beverages must be included and tables must be complete for all nutrients and other bioactive substances of interest.

### Appropriate References

Estimated nutrient intakes must be compared with appropriate references; in the United States and Canada, these are the Dietary Reference Intakes, or DRIs. Their use in dietary assessments is the subject of a recent report (*Dietary Reference Intakes*, 2000).

### Inadequacies, Excesses, and Imbalances May Coexist

In the past, dietary assessments focused on dietary inadequacies. Although these are still relevant, nutrient excesses and imbalances of nutrients also are of concern in most Western countries, and therefore also must be considered. Several of the DRIs are helpful in these respects. DRIs for macronutrients will be published in the near future.

### Appropriate Interpretation of Assessment Results

The estimated average requirement, or EAR, is the nutrient intake estimated to meet the requirement of half the healthy individuals in a particular life stage or gender group. The recommended dietary allowance, or RDA, is the average daily dietary intake that suffices to meet the nutrient requirement of nearly all (97–98 percent) healthy individuals in a particular life stage and gender group. The adequate intake, or AI, is a recommended intake based on observed or experimentally determined approximations or estimates of nutrient intake by a group (or groups) of healthy people whose intakes are assumed to be adequate. The AI is used when an RDA cannot be determined. When the AI's are not based on mean intakes of healthy populations, these values are likely to be less accurate. The tolerable upper intake level (UL) is the highest usual daily nutrient intake likely to pose no risk of adverse health effects to almost all individuals in the general population. As intakes increase above the UL, the risks of adverse effects also increase. The assessment of dietary adequacy is imprecise. A specific individual's actual requirement for a specific nutrient generally is never known. Second, often the number of days that intakes are measured are likely to be insufficient to overcome errors in measuring intake and normal day-to-day variation. Although dietary data alone are not sufficient to assess nutritional status, intakes of individuals can be compared to certain of the DRIs. A usual intake based on a large number of days that is at or above the RDA or AI has a low probability of inadequacy. An intake above the UL places an individual at risk of adverse effects from excessive nutrient intakes. When observed intakes are habitually below the EAR, increased intakes usually are needed because the probability of adequacy is 50 percent or less. Habitual intakes between the EAR and the RDA also

probably need to be improved because the probability of adequacy is less than 97 to 98 percent. Quantitative estimates of risk of inadequacy are more difficult to obtain. However, they can be calculated using methods described in a recent report (*Dietary Reference Intakes*, 2000).

The DRIs also are used to assess the dietary intake of groups. These assessments determine the percentage of individuals whose intakes are estimated to be inadequate. The EAR is used to estimate the prevalence of inadequate intakes within a group. A mean usual group intake at or above the AI implies a low prevalence of inadequate intakes. The UL is used to estimate the percentage of the population at risk of adverse effects from excessive intakes consumed on a chronic basis. Thus, the RDA is not used to assess nutrient intakes of groups.

### Conclusions

Dietary assessment is a necessary component of nutritional status assessment of individuals, and also is useful for other purposes. It can be done using a variety of methods, each of which has advantages and limitations. However, regardless of which method is chosen, it is important that certain criteria be met. Intake from all sources (food, fortified food, beverages, and nutrient supplements) must be included. Sufficient numbers of days to represent usual intakes must be obtained. Complete food and supplement composition tables must be employed. Appropriate reference standards and statistical procedures for assessing intakes must be used. Dietary assessment methods work best in combination with other methods for the assessment of nutritional status.

**DIETARY GUIDELINES.** The 1969 White House Conference on Food, Nutrition, and Health was instrumental in the development of the first set of U.S. dietary guidelines. Specific recommendations emerged out of this conference, which advocated that the government examine more closely the links between diet and chronic disease. The 1969 conference was followed in 1977 by the release of the U.S. Senate Dietary Goals, which summarized specific recommendations for the American diet.

The dietary guidelines are the cornerstone of the federal nutrition policy for the U.S. nutrition programs; thus programs such as food stamps, school lunch/school breakfast, and WIC use the dietary guidelines in developing program services. In addition, all nutrition education programs at the federal level must have messages that are consistent with the dietary guidelines. Thus the impact of the dietary guidelines is wide-ranging. It is estimated that one of every five Americans participates in at least one federal nutrition program.

### History of the Dietary Guidelines for Americans

The Dietary Guidelines attempt to answer the question, "What should Americans eat to stay healthy?" Specifically, the dietary guidelines provide advice for healthy Americans aged two years and older about food choices that promote health and reduce the risk of disease.

The Dietary Guidelines were first developed in 1980 and have been updated every five years since then—1985, 1990, 1995, and 2000. The National Nutrition Monitoring and Related Research Act of 1990 requires the Secretary of Agriculture and Secretary of Health and Human Services (HHS) to publish jointly every five years a report entitled *Dietary Guidelines for Americans*. The report must contain nutrition and dietary information and guidelines for the general public; be based on the preponderance of scientific and medical knowledge current at the time of publication; and be prompted by each federal agency in carrying out federal food, nutrition, or health programs. The 1995 Dietary Guidelines were the first to be statutorily mandated by the U.S. Congress.

Since 1985, USDA and the Department of Health and Human Services have used essentially the same process to prepare the dietary guidelines. An external Dietary Guidelines Advisory Committee (DGAC) has been appointed by the two secretaries to review and revise as necessary the guidelines. The members of the DGAC are widely recognized nutrition and medical experts. A series of public meetings are held to review and discuss the guidelines. Upon completion of the DGAC process, a technical report is sent to the two secretaries and reviewed within the two departments. In addition, in both 1995 and 2000, consumer research was conducted to test consumer reaction to specific design and content elements of the technical report. The consumer research is also used as one element in promoting the dietary guidelines.

### Elements of the Dietary Guidelines

Between 1980 and 1995, the dietary guidelines were relatively stable (Table 1), maintaining seven guidelines. However, the 1995 guidelines reflected some exciting and important changes. More so than ever before, they put an emphasis on total diet; the wording in the 1995 guidelines moved away from individual foods in the direction of a total diet based on variety, moderation, and proportionality. The concept of total diet is reflected symbolically through the graphic of the 1995 Dietary Guidelines bulletin that links all seven guidelines together, anchored around the admonition to "Eat a variety of foods."

In the 1995 guideline on variety, the bulletin stresses a total diet rather than an individual food approach to healthy eating. The recommendation is to choose foods from each of the five major food groups in the Food Guide Pyramid. Also an emphasis is placed on foods from the base of the pyramid (grains) to form the center of the plate accompanied by food from other food groups.

For the first time, the dietary guidelines in 1995 recognized that with careful planning, a vegetarian diet can be consistent with the dietary guidelines and the Recommended Dietary Allowances. The guidelines also present a clear message that food sources of nutrients are preferred to supplements. This "food first" strategy is reinforced by a discussion of other healthful substances present in food, but not in dietary supplements. However, the 1995 guidelines do provide specific examples of situations where dietary supplements may be needed.

The 1995 guidelines also moved more forcefully in the direction of providing a discussion of the direct link between diet and health. Weight gain with age was discouraged for adults. Weight maintenance is encouraged as a first step to achieving a healthy weight. The benefits of physical activity are emphasized. And for the first time, a statement was included on the benefits of moderate alcohol in reducing the risk of heart disease. On this later point, both HHS and USDA were clear that the alcohol guideline was not intended to recommend that people start drinking.

In the 1995 guidelines there was also direct reference to the nutrition education tools that could be used to promote the dietary guidelines. The guidelines explain how consumers can use the three "crown jewels" to build a healthy diet: the Dietary Guidelines, the Food Guide Pyramid, and the Nutrition Facts Label.

The Dietary Guidelines 2000, released by President Bill Clinton in May 2000, break with the tradition of seven guidelines and now include ten separate guidelines. Not only do the Dietary Guidelines 2000 continue to emphasize a total diet approach, they also emphasize a healthy lifestyle. This is reflected clearly in three new concepts that are used as organizing principles for the 2000 Guidelines: "Aim for fitness," "Build a healthy base," "Choose sensibly."

**TABLE 1**

<b>Dietary guidelines for Americans, 1980 to 2000</b>				
<b>1980 7 Guidelines</b>	<b>1985 7 Guidelines</b>	<b>1990 7 Guidelines</b>	<b>1995 7 Guidelines</b>	<b>2000 10 Guidelines</b>
Eat a variety of foods	Eat a variety of foods	Eat a variety of foods	Eat a variety of foods	Let the Pyramid guide your food choices
Maintain ideal weight	Maintain desirable weight	Maintain healthy weight	Balance the food you eat with physical activity—maintain or improve your weight	Aim for a healthy weight
Avoid too much fat, saturated fat, and cholesterol	Avoid too much fat, saturated fat, and cholesterol	Choose a diet low in fat, saturated fat, and cholesterol	Choose a diet low in fat, saturated fat, and cholesterol	Choose a diet that is low in saturated fat and cholesterol and moderate in total fat
Eat foods with adequate starch and fiber and fruits and vegetables	Eat foods with adequate starch and fiber and fruits and vegetables	Choose a diet with plenty of grain, fruit, and vegetable products	Choose a diet with plenty of grain, fruit, and vegetable products	Eat a variety of grains daily, including whole grains Eat a variety of fruits and vegetables daily
Avoid too much sugar	Avoid too much sugar	Use sugars only in moderation	Choose a diet moderate in sugars	Choose beverages and foods to moderate your intake of sugars
Avoid too much sodium	Avoid too much sodium	Use salt and sodium only in moderation	Choose a diet moderate in salt and sodium	Choose and prepare foods with less salt
If you drink alcohol, do so in moderation	If you drink alcoholic beverages, do so in moderation	If you drink alcoholic beverages, do so in moderation	If you drink alcoholic beverages, do so in moderation	If you drink alcoholic beverages, do so in moderation Keep food safe to eat Be physically active each day

There is now a separate guideline for physical activity that states, “Be physically active every day.” In addition to helping to maintain a healthy weight, this guideline also discusses the other health benefits of physical activity. Specific quantitative recommendations are given for amount of physical activity for adults (30 minutes or more) and children (60 minutes or more) per day. For the first time ever there is now a guideline on food safety. Again, this reinforces components of a healthy diet and healthy lifestyle.

The consumer research that was conducted as part of the Dietary Guidelines 2000 process influenced the development of the guidelines. One clear message is that consumers preferred simple, action-oriented guidelines. Thus the guidelines themselves are much more direct and action-oriented as evidenced by: “Aim for a healthy weight!” or “Keep foods safe to eat.”

The guidelines are more consumer-friendly and emphasize practical ways in which consumers can put the concepts into practice. To that end, sections entitled “Advice for Today” are included at the end of each individual guideline and include suggestions on key ways to operationalize the guidelines. The consumer research on the 2000 Dietary Guidelines indicated that consumers particularly liked the Advice for Today section.

### Comparison with Other Dietary Guidelines

A large number of countries—both industrialized and developing countries—have authoritative sets of dietary guidelines. Despite the vastly different geographical and sociocultural contexts of the countries, there are six elements that are common to the sets of dietary guidelines that are in place. Those elements are: (1) Aim for a healthy weight; (2) Let the Food Pyramid guide your choices; (3) Eat a variety of grains daily, especially whole grains; (4) Choose a diet that is low in saturated fat and cholesterol and moderate in total fat; (5) Choose and prepare foods with less salt; (6) If you drink alcoholic beverages, do so in moderation.

A guideline on variety is common, and is often the core element used to reflect the concepts of dietary diversity. The variety ranges from general statements such as, “Eat a variety of foods,” to a very specific quantification, as found in the Japanese guideline, which states that, to obtain well-balanced nutrition with a variety of foods, one should eat thirty foodstuffs a day.

Many of the country-specific dietary guidelines emphasize limiting or moderating total fat and saturated fat intake. Where there is a quantification of limits, this is most commonly a diet containing no more than 30 percent of total energy from fat and less than 10 percent of energy from saturated fat.

Countries typically also include a weight guideline, which emphasizes very clearly the maintenance or achievement of a healthy weight; in the French guideline, there is more specificity indicating individuals should weigh themselves monthly. Most of the dietary guidelines worldwide promote a plant-based diet as the building block of healthful eating. To that end, many countries emphasize grains as the basis of good diet. Reduction of salt and/or sodium is emphasized in a number of the sets of dietary guidelines.

Finally, the issue of alcohol consumption is addressed in many sets of dietary guidelines. There is always a level of caution related to the role of alcohol as part of a healthy diet. The 2000 dietary guidelines for Americans, as an example, indicate that benefits of alcohol in reducing the risk of heart disease can be achieved in other ways, such as maintaining a healthy weight, cessation of smoking, increasing physical activity, and reducing the level of fat and saturated fat in the diet. Indeed, countries like Venezuela go even further and specify: "Alcoholic beverages are not part of a healthy diet" (14).

### Comparison with Disease-Specific Guidelines

A number of professional associations such as the American Heart Association (AHA) and American Cancer Society (ACA) have developed sets of dietary guidelines. Clearly the AHA and ACS have somewhat different objectives in developing their specific sets of guidelines; the American Heart Association guidelines put forward recommendations for a healthful diet, which if followed, reduces the risk of heart disease. Similarly, recommendations from the American Cancer Association are for dietary guidelines which, if followed, reduce the risk of cancer. Given the somewhat different objectives, there is a remarkable degree of similarity in the three sets of guidelines. Here again, the USDA/HHS, the AHA, and the ACA each recommend dietary guidelines related to weight, total saturated fat, salt, and alcohol in moderation as the basis of a healthful diet.

### Guidelines for Children under Age Two

A limited number of countries have some parts of their food-based guidelines devoted to children less than two years of age. In most cases, the advice relates to a discussion of breast-feeding. Australia, for example, states: "Encourage and support breast-feeding." There is similar wording in guidelines from the Philippines and Singapore.

Most industrialized countries rely on national pediatric associations to guide the broad policy recommendations for infant feeding and/or feeding practices for the first two years of life. In almost all cases advice from pediatric associations stresses that human milk is the preferred form of infant feeding.

In devising food-based dietary guidelines for children under two, there is a clear need to segment this

group of children by age groups: birth to 6 months, 6 to 12 months, and 13 to 24 months.

### Future Directions

Worldwide major improvements in public health will be accomplished by an improvement in dietary patterns. Food-based dietary guidelines have been developed in a broad range of countries. A move toward consensus on food-based dietary guidelines is a practical way to develop core elements of global dietary guidelines that can be effectively promoted by individual countries as well as international health organizations.

**DIETARY SYSTEMS: A HISTORICAL PERSPECTIVE.** The urge to classify foods and frame complex dietary laws is as old as civilization itself, if not older. Most dietary systems around the world are explicitly religious. But some dietary systems that arose were more secular in nature; their ultimate goal was to maintain or restore physical health. The most influential of these were produced in Greece, India, China, and the modern West.

The superficial similarity of the ancient systems may have arisen from a common prehistoric root, or they may have influenced each other across trade routes. Separate civilizations also may have arrived at similar ways of describing physiologic functions because some human experiences are universal. The fact that most of these systems assess food qualitatively, using descriptive terms such as hot, cold, moist, and dry, appears to be coincidental. They do not understand or apply these terms in the same way.

### Greece

The Greek dietary tradition stems ultimately from the body of writings attributed to Hippocrates of Cos. Dietary regimen in all these works was considered the most important way to prevent and cure disease, but the concept of diet encompassed much more than food intake. It also considered air quality, exercise, sexual activity, emotions, and the elimination of waste products. Although a fully elaborated theory of the four humors was not yet in place among the Hippocratic writers, in later years and especially in the writings of Galen of Pergamum it came to be the cornerstone of this system. Just as four elements were considered the building blocks of all physical matter, so four basic regulatory fluids were believed to control the human body. These are blood, phlegm, choler, and black bile or melancholy. Each in turn was described as hot and moist, cold and moist, hot and dry, or cold and dry, respectively. Every individual is born with a tendency for one humor to predominate, sometimes excessively so. This was called the complexion, which also was considered affected by age, gender, and a variety of external factors.

The Greeks also classified foods according to their propensity to increase particular humors in the body. Thus cucumbers were considered cold and moist, spices hot and dry. In a body with an abundance or plethora of any given humor, a food or medicine of the opposite quality would act as a corrective. This therefore was an allopathic system that corrected with opposites. The Greeks also were intensely conscious of the texture and consistency of food and how easily it might be broken down and passed through the body.

The Greek system was elaborated upon in several succeeding civilizations, the most important of which were the Byzantine Empire; the Muslim world, which stretched from northern India to Spain; and medieval and Renaissance Europe. Although folk beliefs in Central and South America were influenced by Hippocratic ideas introduced by the Spanish, it appears that an older native system forms the foundation of ideas there.

### India

Ayurvedic medicine is rooted in medical texts known as the *Carakha Samhita*, which may have originated before the first millennium B.C.E. but were written down much later. They include a dietary system still practiced in the twenty-first century. This system bears some similarities to the Greek system, but in practical application it is quite different. Ayurvedic physiology also begins with elements, but it recognizes five: air, fire, water, earth, and space. Each in combination with another creates what is called a *dosha*, a basic life force that governs physiologic functions but not exactly a humor. For example, space and air combine to create the *vata dosha*, which controls movements within the body, such as respiration, circulation, nerve impulses, and even ideas. Fire and water combine to form the *pitta dosha*, which is the principle of digestion and metabolism. Water and earth create the *kapha dosha*, which is the structural principle, giving solidity to the body. Too much or too little of each of these forces causes illness. The key here is a balance. As in the West, individuals are presumed to be born with a certain predilection toward an excess of one *dosha*. This is the *prakriti*, comparable to the concept of complexion in the West.

Just as in the Western system, foods and medicines can increase or decrease the power of any one of the *doshas*. For example, a weak digestion (*pitta*) is improved by heating the body with spicy foods, while an excess of *pitta* causes inflammation and dehydration and is corrected with foods that moisten the body. A weak *kapha dosha* leads to brittle bones and joints, so solid foods that strengthen the body are required.

Another concept in this system is that of the *ojas*, a form of vital energy that supports the immune system. *Ojas* can be increased by meditation and moderate eating but also with special substances like ghee or saffron. Foods also are classified according to their specific virtues or *gunas*, twenty in total, which assign foods values, such as cold or hot, soft or hard, oily or dry, heavy or light,

dull or sharp, solid or liquid. All these terms reflect how food behaves in the body. With an excess of hot *pitta* (digestion), a cold food would be prescribed. With an excess of *vata* (transport), something heavy or dry would be corrective. Like the Greek system, this one is allopathic.

### China

Another major system arose in ancient China, and it too was based on a revered text, in this case *The Yellow Emperor's Classic of Internal Medicine*, composed by one of the so-called celestial emperors, Huang-ti. Probably it was written during the Han dynasty and thus is roughly contemporaneous with the other systems. The first important concept in this system is *qi*, translated as energy, life force, or spirit. *Qi* supports life and helps fight off malign external influences. It also flows through the entire universe, so the individual microcosm is linked to the macrocosm. Health results when the two are in harmony, as do prosperity, peace, and good crops.

The central governing principle in the Chinese system is the opposition of two basic universal forces, yin and yang. Yin is female, dark, cold, soft, empty, night. Yang is male, light, warm, firm, full, day. Universal as well as physical harmony depends on a balance of these two forces. In addition, phases or processes of transformation in nature, not exactly elements as building blocks of nature, exist. Here too are five: earth, fire, wood, metal, and water. As processes of change, they govern, for example, generation. Water makes trees grow, wood burned creates fire, fire creates ash. Earth is the source of metals, and metals flow like water when heated.

All physiological functions can be described in terms of these transformations, like breaking down and processing foods. Specific foods or drugs aid a particular process, build up good *qi*, or promote the flow of *qi* through the body, as does acupuncture. Just as in the other systems, this is a holistic medicine that takes into account exercise, air quality, sleep patterns, sexual activity, and of course diet to keep the yin and yang forces in balance, the *qi* flowing, and physiological transformations in good order. The idea that certain foods are heating, cooling, drying, or moistening appears to have been imported from India around the sixth century C.E.

### The Modern West

The modern concept of diet is much narrower than in the ancient systems, for it is concerned merely with food intake, calories, vitamins, and the like. Little consideration is given to the holistic aspect of living in harmony with external influences. Diet is not carefully prescribed according to the individual's unique complexion and habits. Calorie needs are defined by the rate at which energy is expended. All bodies are assumed to require the same nutrients of a specified range to allow for genetic and other sources of variation. This line of reasoning stems from envisioning the body as an engine fueled by food, a concept that arose in the nineteenth century fol-

lowing the research of the chemist Antoine-Laurent Lavoisier and later of Justus von Liebig. Only with the discovery of vitamins in the early twentieth century was this transformation complete. The concept of diet also was defined more narrowly as food intake or as a strict regimen intended to promote weight loss.

**DIETETICS.** Dietetics is the integration and application of principles derived from several disciplines—including nutrition, biochemistry, physiology, food science and composition, management, food service, and the behavioral and social sciences—to achieve and optimize human health. Dietetic professionals translate the scientific evidence regarding human nutrition and use that information to help shape the food intake or choices of the public (ADA, 2002).

Dietetic professionals work with individuals and groups of all ages to assess nutritional health and provide recommendations and therapies to assist individuals, groups, and populations in achieving a diet based on scientific evidence. The diet is generally a variety of foods but may include supplements and tube or parenteral feedings. Nutrient needs vary based on age, genetics, body composition, health status, and lifestyle. Dietetic professionals specialize in different aspects of care: They serve as translators of nutrition science to the public, as specialists in business and industry, as advocates to change food policy, as managers of food operations, as educators and researchers, and as clinicians in many different settings.

### Education of Dietetic Practitioners

The majority of dietetics professionals are registered dietitians (R.D.s) and members of the American Dietetic Association. These individuals have various job titles including but not limited to dietitian, nutritionist, medical nutrition therapist, food service director, and public health or community nutritionist. The R.D. signifies that the individual has completed an academic education leading to at least a B.S. in dietetics, with coursework in

nutrition, social sciences, biological sciences, and food science, along with a planned clinical experience conducted under supervision for at least six months, and has passed a national credentialing examination. The credentialing examination for the R.D. was introduced in 1969. The education and clinical experience components were first established in 1927. In 2002, about 41 percent of R.D.s had master's degrees and about 4 percent had doctorates (Bryk and Soto).

Established in the early 1980s, a two-year credential as a dietetic technician registered (D.T.R.) involves the same three-prong approach of education, experience, and examination. The D.T.R. functions clinically under the supervision of an R.D., and often manages a food-service operation. The D.T.R. has a more limited scientific education, but has similar management skills. The accreditation of entry-level dietetics programs is done by the Commission on Accreditation for Dietetic Education, and the credentialing is under the Commission on Dietetic Registration. In 2002 there were about 75,000 R.D.s or D.T.R.s in the United States.

### The Evolution of Dietetic Professionals

The American Dietetic Association was founded in 1917. Its immediate goal was to assist in the feeding of World War I soldiers and to “benefit as many as possible.” At that time, preventing deficiencies and providing enough food to support health were key goals. The feeding of institutionalized patients in hospitals and sanitariums quickly followed, as well as the provision of diet therapy for conditions such as diabetes mellitus and nephritis. In the 1940s, recommended dietary allowances (RDAs) were introduced, setting a standard in gauging what to feed groups; the RDAs were established to feed populations, not individuals. At the same time, the role of diet therapy was expanding. By the 1960s, understanding of the role of nutrition in the treatment of chronic diseases such as cardiovascular disease was emerging. Dietetic professionals were designing formulas for feeding patients via tubes and evaluating the composition and consistency of commercial tube-feedings that were beginning to be introduced.

In the 1970s the role of dietetic professionals expanded to include assessing the nutritional health of hospitalized patients and recommending feeding based on this assessment. Dietetic professionals began to educate the public on the use of food labeling to encourage eating properly, and to place emphasis on the use of nutrition to prevent chronic disease. Programs such as WIC (the federal Women, Infants, and Children nutrition program) expanded the dietetic practitioners' role in women's and children's health. During the 1970s roles for dietetic practitioners diversified, with dietitians working in dialysis centers, in rehabilitation, in marketing and public relations firms, and for food companies. Within the American Dietetic Association, practice groups formed to meet needs in specialty areas, for example, taking consulting roles in long-term care facilities and nutrition support roles in hospitals. During the 1980s roles continued to expand, and specialty credentials in diabetes, nutrition support, renal care, and pediatrics were introduced. The 1990s saw an expansion into outpatient care, expanding private-practice opportunities, and a movement to cross-train and become multitasked.

Medicare part B reimbursement for nutrition counseling of nondialysis renal patients and individuals with diabetes mellitus was introduced in January 2002. It is anticipated that reimbursement would expand to cover counseling for other conditions. Private insurance coverage for medical nutrition therapy is also increasing as proper diet and lifestyle are recognized as key elements in maintaining or enhancing the health of the American public. The role of the dietetic professional continues in managing disease, has expanded in prevention, and will expand to include forecasting disease as the impact of genetics research reaches health care. As Americans eat out more and purchase more prepared foods, the role of the dietitian in dining establishments and supermarkets should expand.

The early twenty-first century is witnessing a focus on enhancing well-being and physical strength and stamina through nutrition. The dietetics profession promotes a total-diet approach to nutrition, with balance, variety, and moderation key to successful nutrition health. The newest aspects of dietetic and nutrition counseling include functional foods (that is, foods that are modified to provide a health benefit beyond the food's traditional nutrients) to enhance health, the use of dietary supplements, and the integration of alternative products such as botanicals. Dietetic practitioners assist individuals in determining if products are beneficial, whether research has been too limited to be determinative, or if the products may in fact be detrimental. Opportunities for research on the value of these products in promoting health abound. With technological advances in data collection and storage, better analysis of dietary intakes should contribute to a better understanding of the role of nutrition in health and disease.

### Summary

Dietetic practitioners translate the science of nutrition into practical applications for individuals, groups, and communities. This requires a solid foundation in cultural competency, including knowledge of food composition, preparation methods and cultural values associated with particular foods, and skills in the culinary arts as well as in nutrition, science, social sciences, management, and communications. Dietetic practitioners will continue to provide nutrition therapy to individuals and groups, manage the feeding of individuals and groups, provide public education, and contribute to research about the links between food, nutrition, and health. Dietetic practitioners have a major contribution to make in the public-policy debate on issues such as obesity and its prevention and management, hunger and its prevention, and genetic modification of foods. The role of dietetic professionals will expand as nutrition becomes a major focus in addressing health issues in the nation and the world.

**DIGESTION.** Digestion can occur at many levels in the body; generally, it refers to the breakdown of macro-

molecules or a matrix of cells, or tissues, into smaller molecules and component parts. This particular section will focus on digestion of food in the gastrointestinal tract: the process that is required to obtain essential nutrients from the food we eat. The gastrointestinal tract (GIT) is a highly specialized organ system that allows humans to consume food in discrete meals as well as in a very diverse array of foodstuffs to meet nutrient needs. Figure 1 contains a schematic of the GIT and illustrates the organs of the body with which food comes into contact during its digestion. These organs include the mouth, esophagus, stomach, small intestine, and large intestine; in addition, the pancreas and liver secrete into the intestine. The system is connected to the vascular, lymphatic, and nervous systems; however, the function of these systems in gastrointestinal physiology is beyond the scope of this article, which focuses primarily on the process of breaking down macromolecules and the matrix of food.

### Mechanical Aspects of Digestion

Food is masticated in the mouth. Chewing breaks food into smaller particles that can mix more readily with the GIT secretions. In the mouth, saliva lubricates the food bolus so that it passes readily through the esophagus to the stomach. The sensory aspects of food stimulate the flow of saliva, which not only lubricates the bolus of food but is protective and contains digestive enzymes. Swallowing is regulated by sphincter actions to move the bolus of food into the stomach. The motility of the stomach continues the process of mixing food with the digestive secretions, now including gastric juice, which contains acid and some digestive enzymes. The action of the stomach continues to break down food into smaller particles prior to passage to the intestine. The mixture of food and digestive juices is referred to as digesta, or chyme. The stomach, which after a meal may contain more than a liter of material, regulates the rate of digestion by metering chyme into the small intestine over several hours. Several factors can slow the rate of gastric emptying; for example, solids take longer to empty than liquids, mixtures relatively high in lipid take longer to empty, and viscous, or thick, mixtures take longer to empty than watery, liquid contents.

In the upper part of the small intestine, the duodenum, receptors appear to influence the rate of gastric emptying either through hormonal or neural signals. Peristaltic motor activity in the small intestine propels chyme along the length of the intestine, and segmentation allows mixing with digestive juices in the intestine, which include pancreatic enzymes, bile acids, and sloughed intestinal cells. Digestion of macronutrients, which began in the mouth, continues in the small intestine, where the intestinal surface provides an immense absorptive surface to allow absorption of digested molecules into circulation. While the intestine from the outside appears to be a tube, the lining of the inner surface contains tissue folds and villi that are lined with intestinal cells,

each with microvilli, or a brush border, which greatly amplify the absorptive surface. The intestinal cells can absorb compounds by several cell membrane-mediated transport mechanisms and then transform them into compounds, or complexes, that can enter circulation through the blood, or lymphatic, system.

What is not digested and absorbed passes into the large intestine. In this organ, water and electrolytes are reabsorbed, and the movements of the large intestine allow mixing of the contents with the microflora of bacteria and other microbes that are naturally present in the large intestine. These microbes continue the process of digesting the chyme. Eventually the residue enters the rectum and the anal canal, and stool is formed, which is defecated. Transit time of a non-digestible marker from mouth to elimination in the stool varies considerably: normal transit time is typically twenty-four to thirty-six hours, but can be as long as seventy-two hours in otherwise healthy individuals.

### **Breakdown of Macromolecules in Foods**

Foods are derived from the tissues of plants and animals as well as from various microorganisms. For absorption of nutrients from the gut to occur, the cellular and molecular structure of these tissues must be broken down. The mechanical actions of the GIT help disrupt the matrix of foods, and the macromolecules, including proteins, carbohydrates and lipids, are digested through the action of digestive enzymes. This digestion produces smaller, lower molecular weight molecules that can be transported into the intestinal cells to be processed for transport in blood, or lymph.

Proteins are polymers of amino acids that in their native structure are three-dimensional. Many cooking or processing methods denature proteins, disrupting their tertiary structure. Denaturation, which makes the peptide linkages more available to digestive enzymes, is continued in the stomach with exposure to gastric acid. In addition, digestion of the peptide chain begins in the stomach with the enzyme pepsin. Once food enters the small intestine, enzymes secreted by the pancreas continue the process of hydrolyzing the peptide chain either by cleaving amino acids from the C-terminal end, or by hydrolyzing certain peptide bonds along the protein molecule. The active forms of the pancreatic enzymes include trypsin, chymotrypsin, elastase, and carboxypeptidase A and B. This process of protein digestion produces small peptide fragments and free amino acids. The brush border surface of the small intestine contains peptidases, which continue the digestion of peptides, either to smaller peptide fragments or free amino acids, and these products are absorbed by the intestinal cells.

Carbohydrates are categorized as digestible or non-digestible. Digestible carbohydrates are the various sugar-containing molecules that can be digested by amylase or the saccharidases of the small intestine to sugars that can be absorbed from the intestine. The predomi-

nant digestible carbohydrates in foods are starch, sucrose, lactose (milk sugar), and maltose. Glycogen is a glucose polymer found in some animal tissue; its structure is similar to some forms of starch. Foods may also contain simple sugars such as glucose or fructose that do not need to be digested before absorption by the gut. Alpha amylase, which hydrolyzes the alpha one to four linkages in starch, is secreted in the mouth from salivary glands and from the pancreas into the small intestine. The action of amylase produces smaller carbohydrate segments that can be further hydrolyzed to sugars by enzymes at the brush border of the intestinal cells. This hydrolysis step is closely linked with absorption of sugars into the intestinal cells.

Non-digestible carbohydrates cannot be digested by the enzymes in the small intestine and are the primary component of dietary fiber. The most abundant polysaccharide in plant tissue is cellulose, which is a glucose polymer with beta one to four links between the sugars. Amylase, the starch-digesting enzyme of the small intestine, can only hydrolyze alpha links. The non-digestible carbohydrates also include hemicelluloses, pectins, gums, oligofructose, and inulin. While non-digestible, they do affect the digestive process because they provide bulk in the intestinal contents, hold water, can become viscous, or thick, in the intestinal contents, and delay gastric emptying. In addition, non-starch polysaccharides are the primary substrate for growth of the microorganisms in the large intestine and contribute to stool formation and laxation. Products of microbial action include ammonia, gas, and short-chain fatty acids (SCFA). SCFA are used by cells in the large intestine for energy and some appear in the circulation and can be used by other cells in the body for energy as well. Thus, while dietary fiber is classified as non-digestible carbohydrate, the eventual digestion of these polysaccharides by microbes does provide energy to the body. Current research is focused on the potential effect of SCFA on the health of the intestine and their possible role in prevention of gastrointestinal diseases.

For dietary lipids to be digested and absorbed, they must be emulsified in the aqueous environment of the intestinal contents; thus bile salts are as important as lipolytic enzymes for fat digestion and absorption. Dietary lipids include fatty acids esterified to a glycerol backbone (mono-, di- or triglycerides); phospholipids; sterols, which may be esterified; waxes; and the fat-soluble vitamins, A, D, E, and K. Digestion of triglycerides (TG), phospholipids (PL), and sterols illustrate the key factors in digestion of lipids. Lipases hydrolyze ester bonds and release fatty acids. In TG and PL, the fatty acids are esterified to a glycerol backbone, and in sterols, to a sterol nucleus such as cholesterol. Lipases that digest lipids are found in food, and are secreted in the mouth and stomach and from the pancreas into the small intestine. Lipases in food are not essential for normal fat digestion; however, lipase associated with breast milk is especially important for newborn infants. In adults

the pancreatic lipase system is the most important for lipid digestion. This system involves an interaction between lipase, colipase, and bile salts that leads to rapid hydrolysis of fatty acids from TG. An important step in the process is formation of micelles, which allows the lipid aggregates to be miscible in the aqueous environment of the intestine. In mixed micelles, bile salts and PL function as emulsifying agents and are located on the surface of these spherical particles. Lipophilic compounds such as MG, DG, free sterols, and fatty acids, as well as fat-soluble vitamins, are in the core of the particle. Micelles can move lipids to the intestinal cell surface, where the lipids can be transported through the cell membrane and eventually packaged by the intestinal cells for transport in blood or lymph. Most absorbed lipid is carried in chylomicrons, large lipoproteins that appear in the blood after a meal and which are cleared rapidly in healthy individuals. Bile salts are absorbed from the lower part of the small intestine, returned to the liver, and resecreted into the intestine, a process referred to as enterohepatic circulation. It is important to note that bile salts are made from cholesterol, and drugs such as cholestyramine or diet components such as fiber that decrease the amount of bile salt reabsorbed from the intestine help to lower plasma cholesterol concentrations.

### Regulation of Gastrointestinal Function

Regulation of the gastrointestinal response to a meal involves a complex set of hormone and neural interactions. The complexity of this system derives from the fact that part of the response is directed at preparing the GIT to digest and absorb the meal that has been consumed in an efficient manner and also at signaling short-term satiety so that feeding is terminated at an appropriate point. Traditionally, physiologists have viewed the regulation in three phases: cephalic, gastric, and intestinal. In the cephalic phase, the sight, smell, and taste of foods stimulates the secretion of digestive juices into the mouth, stomach, and intestine, essentially preparing these organs to digest the foods to be consumed. Experiments in which animals are sham fed so that food consumed does not actually enter the stomach or intestine demonstrate that the cephalic phase accounts for a significant portion of the secretion into the gut. The gastric and intestinal phases occur when food and its components are in direct contact with the stomach or intestine, respectively. During these phases, the distension of the organs with food as well as the specific composition of the food can stimulate a GIT response.

The GIT, the richest endocrine organ in the body, contains a vast array of peptides; however, the exact physiological function of each of these compounds has not been established. Five peptides, gastrin, cholecystokinin (CCK), secretin, gastric inhibitory peptide (GIP), and motilin are established as regulatory hormones in the GIT. Multiple aspects have been investigated to under-

stand their release and action. For example, CCK is located in the upper small intestine; protein and fat stimulate its release from the intestine, while acid inhibits its secretion. Once released, it can inhibit gastric emptying and stimulate secretion of acid and pancreatic juice and contraction of the gall bladder. In addition, it stimulates motility and growth in the GIT and regulates food intake and insulin release. Among the other established gastrointestinal peptides, secretin stimulates secretion of fluid and bicarbonate from the pancreas, gastrin stimulates secretion in the stomach, GIP inhibits gastric acid secretion, and motilin stimulates the motility of the upper GIT. In addition to investigating the various factors causing release of these hormones and the response to them, physiologists are also interested in the interactions among hormones as well as those with the nervous system, since the response to a meal involves release of many factors.

Obtaining food and digesting it efficiently are paramount to survival. The human GIT system most likely evolved during the period when the species acquired its food primarily through hunting and gathering. The overlapping regulatory systems, combined with an elevated capacity to digest food and absorb nutrients, insured that humans used food efficiently during periods in which scarcity might occur.

**DINNER.** Dinner is the important meal in the daily or another cycle of meals, typically requiring more formal culinary arrangements, table trappings, and etiquette, and probably more abundant foods and drinks. While rural households have tended to share the main daily meal during daylight hours, industrial societies have pushed dinner into the evening, thereby making this meal more important than breakfast, lunch, tea, subsequent supper, or any intervening or alternative snack. Major meals within weekly, monthly, and annual cycles are often identified as "dinner" (Sunday meals, Christmas, and Thanksgiving). However, with rites of passage, dinner's importance may be transcended by something grander: a banquet, feast, wake, or wedding breakfast.

In the West, all family members attend the conventional dinner. In religious homes, the meal may be offered with grace. In some patriarchal versions of the family dinner, the head of the family sits in a carver (chair with arms) at one end of the table while a woman (generally the wife)

A large dinner given by the Third Army Corps Union for former commander Major General D. E. Sicles at Delmonico's in New York, February 22, 1873. It was not customary in this period for women to be present at such "public" meals. FROM FRANK LESLIE'S ILLUSTRATED NEWSPAPER, MARCH 2, 1873. © CORBIS.

serves the meal. The household might bring out a special set of matching crockery or "dinner service," especially when guests are in attendance. A succession of courses is served that often centers on a meat dish—most impressively, turkey, prime rib, or spring lamb—and some occasions conclude with a dessert course.

Beyond immediate family gatherings, a dinner can be elaborate, involving written invitations, keen anticipation (or dread) on the part of the guests, and requiring toasts and speeches. On such formal occasions, diners wear special clothing, such as a dinner jacket or tuxedo for men. As it is maintained by dedicated food-and-wine societies, dinner extends through many courses of exquisite foods and matching drinks. Courting couples become acquainted over restaurant dinners and cook together for newly shared friends. Homecomings, departures, graduations, new jobs, business deals, and the like are ready excuses for a dinner date, often outside the home.

In the language of anthropologist Mary Douglas in her essay "Deciphering a Meal," dinner is a "stressed"

event. She found her everyday, culinary pattern to be "one element stressed accompanied by two or more unstressed elements" (p. 67), that is, she cooked one main meal (dinner) and two minor meals (breakfast and lunch). Further, dinner tended to comprise one main and two minor dishes, and each dish had one centerpiece food and two accompaniments. This approach to dinner was no more than the pattern within a "certain segment of the middle classes of London" when Douglas wrote in 1972.

Meals are highly culturally variable, with one, two, three, four, or more meals per day being quite common. Meals vary considerably in timing and format, with fixed hours being a modern obsession. The daily meal routine differs among town and country settings, social classes, and between the sexes. In ancient times, monarchs dined behind screens as the gods had done; then they came to sit in full view or "in state." Women and men have dined apart in many cultures, perhaps in separate rooms or with the men going "out," leaving women and children at home. Women and men have also alternated flirtatiously

around tables as “roses and thorns.” The patterns of dining of present-day diners and their immediate forebears have remained constantly in flux.

Given the difficulty of establishing general principles of dinner, let alone transferring the concept to other cultures, this entry concentrates on a recognizable Western tradition that took shape in the nineteenth century. During that time, wealthy families agreed on smaller evening dinner parties, while working-class families gathered in their homes for dinner after a hard day at work or school. Much gastronomic attention has been devoted to this central social occasion, yet as meals are always evolving, questions arise regarding dinner’s survival.

### The Invention of Dinner

Throughout history, city dwellers tended to dine later and longer. Also, many travelers made the evening meal their main meal, as this was the time when they and their horses generally settled into an inn. In agrarian communities, however, where work began at daybreak, the first and principal meal occurred in the middle of the day. In medieval Europe, this midday meal was ideally eaten at the ninth hour after sunrise or “none,” from which the word “noon” derives its meaning. This meal might have been taken in the fields and, especially in hotter climates such as the Mediterranean, been followed by a siesta.

President Thomas Jefferson illustrated the typical routine of an eighteenth-century rural gentleman. During his retirement at his home Monticello, he had two main meals per day: breakfast at around 9:00 A.M. and dinner at around 4:00 P.M. In a letter to Thaddeus Kosciuszko on 26 February 1810, Jefferson described this routine: “My mornings are devoted to correspondence. From breakfast to dinner I am in my shops, my garden, or on horseback among my farms; from dinner to dark, I give to society and recreation with my neighbors and friends; and from candle-light to early bed-time I read.”

Consuming two substantial meals—a late breakfast and a dinner (around 3:00 or 4:00 P.M. in the country and as late as 6:00 P.M. in town)—was also the pattern in England. During the nineteenth century, however, Arnold Palmer indicates that mealtimes became very uncertain. Eventually 8:00 P.M. became fashionable for dinner, a move that was in response to the longer business day and later parliamentary and court sittings. Workplaces were increasingly located at a greater distance from households, making it harder to return home for a main meal before work ended. This change was not a problem, as the evening meal was more easily lit with gas and electricity rather than the candles of the previous centuries. A more substantial luncheon occurring around 12:30 or 1:00 P.M. eventually filled the emerging hole in the middle of the day.

Confirming a similar pattern in the United States, Harvey A. Levenstein claims in *Revolution at the Table* that a new fascination with sophisticated food helped move

dinner well into the evening. Before the 1870s, dinner-time was usually in the early or mid-afternoon, followed by tea and supper. In the last quarter of the nineteenth century, however, “upper-class males liked at least to appear to be engaging in productive activities during the day” and wanted their main meal afterward (p. 17).

Meanwhile, the emerging working class settled into their principal meal immediately after work, which was generally around 6:00 P.M. In the new world of highly differentiated production and consumption, social reformers and others, often with religious motivations, depicted the ideal family around their humble but sufficient table—the husband having put food there through his honest labors and the good woman through her thrifty shopping.

A similar movement occurred in France and was detailed in “Food Allocation of Time and Social Rhythms” in the journal *Food and Foodways*. The social elite used the same words for meals for several centuries, but they fluctuated in times, content, and relative importance. Most strikingly, each meal gradually moved later in the day until it replaced the next one. In particular, dinner (*dîner*) shifted from around 10 A.M. in 1550 until it reached late afternoon around the time of the Revolution, finally replacing supper (*souper*), which had previously been shifted from late afternoon to evening (p. 268). As a further complication, the schedule differed between social classes so that, according to a mid-nineteenth-century account, “the people *déjeune*, the bourgeoisie dines, the nobility sups. A man’s stomach gets up earlier or later depending on his distinction” (p. 210). The French word *déjeuner* has been left untranslated rather than choosing between “breakfast” and “lunch.”

A second major change in the wealthy European table contributed to the emergence of a recognizably modern dinner. This was the replacement of a series of grand tableaux of dishes, which servants would offer around, called *service à la française* (French service), with the succession of individually plated dishes, often served at smaller tables. This type of service was termed *service à la russe* (Russian service).

“Dinner, being the grand solid meal of the day, is a matter of considerable importance; and a well-served table is a striking index of human ingenuity and resource,” extolled Isabella Beeton in 1861 in the long-lasting English “bible,” the *Book of Household Management in London* (p. 905). In her sample “Bills of Fare,” breakfasts warrant a mere half-page, although this is twice as much as luncheons. Three pages are devoted to “Ball Suppers” for sixty persons. In comparison, dinners occupy forty-seven pages. This section lists each month’s menus, which are divided into five successive sets of dishes: “First Course” (soups and fishes); “Entrees” (various “made” meat dishes, such as pork chops and lobster ragout); “Second Course” (impressive meats such as roasts, hams, and pies); “Third Course” (game “removed” or replaced by sweet dishes); and “Dessert” (fruits and ices). Diagrams show

how each course is to be arrayed on the table around the central vase of flowers.

In deference to the direction in which dinner was heading, Beeton's book has a few concluding suggestions on *service à la russe*. The menus run through a simplified version of the *service à la française* progression that would become the standard dinner, namely, soup, fish, meat, and dessert. (Evocatively, the four courses make an evolutionary ascent from the primordial stew to the ethereal.) Yet confusion rules because, to cite one small complication, the British and Australian "entrée" precedes the main dish, which is the "entrée" for Americans. Cheese is a common additional course, before dessert in the French system and after dessert in the English.

In addition, Beeton's monthly suggestions conclude with "Plain Family Dinners," where she gives two menus for each day of the week. These comprise either two dishes (a meat dish plus sweet pudding) or, more often, three (with the addition of preliminary soup or fish dish). In the early twenty-first century, three-course dinners remain standard. For example, in the American classic *Joy of Cooking*, the successors to Irma S. Rombauer suggest lunch and dinner menus, both possibly with only two courses, whereas dinner usually has three (pp. 22–23). Lunch is lighter and more likely to include something obviously ethnic, particularly Italian (for example, minestrone). Dinner perhaps opens with soup (Greek lemon soup), salad, or fish, followed by a meat dish (lamb chops with roast garlic and cognac) accompanied by perhaps two vegetable dishes (pommes Anna, turnip purée) or rice or sometimes bread. Both lunch and dinner conclude with a tart, cake, or other dessert (such as apple spice cake).

The gastronomic literature that blossomed in the early nineteenth century promoted the intimate bourgeois supper that became the modern dinner. Writers of this period stressed the dependence on a good cook, the host's responsibility for the well-being of guests, the guests' responsibility to be punctual, and the optimum number at table in order to preserve "general" (that is, shared) conversation. Instead of large, aristocratic gatherings, the ideal number of guests became "not fewer than the graces [three] nor more than the muses [nine]."

Jean Anthelme Brillat-Savarin, who published *The Physiology of Taste* in 1825, assumed that a dinner (*dîner*) could be the "last affair of the day" and should conclude between 11:00 P.M. and midnight. Brillat-Savarin's "Meditation 14" includes twelve rules to optimize the "pleasure of the table," such as a room temperature between 13–16 degrees Réaumur (around 60–68°F), a progression from the most substantial foods to the lightest, and from the simplest wines to the most heady, and so on. Guests had to number "no more than twelve, so that conversation may always remain general," although he plainly enjoyed even smaller dinners that met just four conditions: "food at least passable, good wine, agreeable companions, and enough time" (1949, pp. 192–193).

A decade later, in London, Thomas Walker wrote about "aristology," or the art of dining, in his weekly newspaper *The Original*. In urging that dinner invitations make clear who is attending and what will be served, Walker included: "we shall sit down to table at half-past seven," yet he preferred the old system of an afternoon dinner (with male colleagues) and a separate supper as an opportunity for "wit, brilliancy and ease." As for guests, he stated: "Eight I hold to be the golden number, never to be exceeded without weakening the efficacy of concentration."

Walker's enthusiasm was not restricted to simplifying the dinner of the wealthy. As a police magistrate, he believed that the cure for poverty was self-dependence, which required the cultivation of domestic economy. In the "cheerless home," he wrote, the wife was absent or intoxicated, and possessions were often taken to the pawnbrokers. Coming home to angry words, then blows, the husband fled to the public house, where the wife came to collect him but also tended to stay herself. Meanwhile, in the "well-ordered" home, the returning husband found a "kindly woman, a cheerful fire, quiet children, as good a meal as his means will allow, ready prepared, every want anticipated."

The ideal of the modern dinner—ranging in style from the elegant dinner party to the virtuous, homely repast—was in place before the twentieth century. The advocates of this ideal helped set the stage for the "proper meal," to which British diners became committed, as evidenced in surveys such as *Women, Food, and Families* by Nickie Charles and Marion Kerr. People expected a hot course of "meat and two veg," which would be cooked by the mother or wife. However, dinner's relatively stable form was already breaking up again.

### Disintegration

In the early twenty-first century, Sunday dinner has been giving way to more casual alternatives, notably brunch. Except for the exceptional "dinner party," the evening meal has become less rigid in expected fare, manners, and even attendance. Where morning newspapers had once intruded upon breakfast, prime-time television now interrupts dinner conversation. With both parents having to work, children often turn into individualistic snackers.

The conventional dinner has been perhaps an unnecessarily private refuge of the nuclear family or a showplace for privilege, with items such as fabulously expensive wines. The expansion of the food-service industry with street outlets, informal cafés, and restaurants has opened up an often more pluralistic, democratic marketplace that has restored the street life of the past. Yet many studies have demonstrated that family dinners assist in the socialization of children; psychological research has found that children who share meals are better adjusted and do better at school. At the same time, epidemiological studies (some of which are summarized in the article by James S. House and colleagues) have sug-

gested that people who share meals with others live longer than solitary eaters. Treating late twentieth-century meal trends as alienating, Australian gastronomic author Michael Symons argues in *The Shared Table* for more “authenticity,” in the sense of meals that bring people closer to each other and their physical world; that is, dinner makes us human.

These are not trifling particulars, as Thomas Walker, in *The Original* on Wednesday, 9 September 1835, maintained:

Dining is an occurrence of every day of our lives, or nearly so, and as our health and spirits depend in great measure upon our vivid enjoyment of this our chief meal, it seems to me a more worthy object of study than those unreal occupations about which so many busy themselves in vain.

**DISEASE: METABOLIC DISEASES.** Metabolism may be defined as those changes in liver cells that provide energy for vital processes. “Metabolic diseases” is a term that includes a vast array of genetic disorders

whose effects may be exacerbated or ameliorated by diet. Several groups of these are recognizable and treatable.

One group of metabolic diseases is concerned with errors in the body that fail to preserve equilibrium of the water and salts. Dehydration results from excess water loss compared to intake. Normally, this is compensated for by thirst and the subsequent ingestion of water. Diseases result from loss of the thirst mechanism; excessive water is lost with diseases of the kidney or of the pituitary gland (diabetes insipidus). Diseases of the sweat glands may result in excessive loss of salt. Shock due to low salt in the circulation may occur as a normal blood pressure is not maintained.

Cystic fibrosis of the pancreas is a severe metabolic disease caused by an abnormality of a gene on chromosome 7. Infants may be born with obstruction of the intestine, develop severe diarrhea and/or chronic lung disease, or fail to grow properly. At present, treatment includes special easily absorbable formulas, large doses of vitamins, supplements of enzymes that are made in the pancreas, and frequent administration of specific antibiotics to treat or prevent lung infection.

Salt is lost in patients with the genetic disease cystic fibrosis, an error in one aspect of the function of the pancreas. Loss of function or destruction of pancreatic islet cells, another part of the pancreas, causes type 1 diabetes mellitus, one of the severe common metabolic diseases. The islets of the pancreas are the source of insulin, a hormone responsible for the metabolism of sugar. Without insulin, sugar (glucose) rises in the blood and is excreted in the urine together with excessive water and salt (sodium and chloride). Dehydration results in loss of excess sodium (a base or alkali) and results in the tissues becoming acidotic and the body is in “acidosis.” Treatment requires administration of fluids and an excess of sodium compared to chloride (chloride functions as an acid in the body). Because insulin functions in fat metabolism, patients with diabetes may develop atherosclerosis, heart disease, and other complications due to abnormal deposition of fat. The amount of carbohydrate, protein, and fat in the diet must be regulated even in those receiving regular amounts of insulin.

In addition to the pancreas, disturbed function of any of the endocrine glands may result in metabolic disease. For example, the pituitary gland secretes growth hormone. Excessive growth hormone results in gigantism and acromegaly (i.e., overgrowth of parts of the body or the whole body, e.g., progressive enlargement of hands, feet, and face). Deficiency of growth hormone results in dwarfism. The thyroid gland secretes thyroxine, a hormone that controls metabolic rate. Excessive thyroxine results in excessive burning of calories, and affected children fail to thrive (Graves’s disease). Insufficiency results in hypothyroidism. In the baby, this may be called cretinism (physical shortness and mental deficiency), and in the older child, myxedema (form of inelastic swelling of

the connective tissue). If not treated, these children may be mentally retarded and fail to grow properly. The adrenal glands secrete hormones for maintaining blood pressure. Lack of adrenal function may result in shock. The adrenal glands also are important in sugar metabolism and lack of function may result in low blood sugar (hypoglycemia). Abnormalities of the fetal adrenal glands result in abnormalities of the development of the sexual characteristics and in hypotension or low blood pressure. The parathyroid glands are essential for normal bone function and metabolism. Abnormalities may result in a ricketslike syndrome, or in low blood calcium that may cause seizures. Abnormalities of the ovaries or testes result in abnormalities in sexual development. Abnormalities due to endocrine deficiencies may be corrected by replacement hormones. For those with excessive hormone secretion, surgery or treatment with drugs to inhibit the secretion of the hormone may be effective.

### Vitamins

Inappropriate vitamin intake also causes metabolic disease. Vitamin A deficiency results in blindness; night blindness is due to lack of a specific metabolic product, rhodopsin, of vitamin A. Excessive vitamin A may result in increased intracranial pressure due to abnormalities of metabolism of cerebral spinal fluid. Thiamine is necessary for carbohydrate metabolism, and lack of thiamine results in beriberi, a very severe disease involving edema and heart failure. Some people with thiamine deficiency develop central nervous system abnormalities. Niacin is necessary for carbohydrate metabolism. Deficiency results in pellagra, a condition marked by diarrhea, abnormal coloration of the skin, central nervous system abnormalities, and death. Pyridoxine, vitamin B<sub>6</sub>, is necessary for nerve and other functions. Deficiency results in seizures, abnormal sensation in the hands and feet, and anemia. Biotin is necessary for protein and fatty acid metabolism. Deficiency of biotin results in abnormalities of the hair and skin. Deficiency may occur in those who eat significant amounts of raw eggs. Deficiency of folic acid results in anemia. Deficiency in a pregnant woman results in a fetus with abnormalities of the spinal cord (e.g., spina bifida, myelomeningocele). Vitamin B<sub>12</sub> deficiency results in abnormalities of nucleotides that are essential for gene replication and transcription. Clinically, vitamin B<sub>12</sub> deficiency manifests as pernicious anemia, which, in addition to anemia, includes abnormalities of the central nervous system. Vitamin C (ascorbic acid) is necessary for the metabolism of interstitial (collagen) support substance. Deficiency results in bleeding, bone pain, and scurvy. Vitamin D is necessary for calcium metabolism. Deficiency results in abnormal bone formation and rickets. Deficiency also may result in secondary hypoparathyroidism, low serum calcium, and seizures. Excess may result in abnormal deposition of calcium in the kidneys and brain resulting in kidney failure and brain abnormalities. Vitamin E participates as an antioxidant. Vitamin K functions in clotting mechanism and bone

metabolism. Treatment of any of the vitamin deficiencies or excesses requires control of intake, unless due to primary metabolic diseases that may inhibit absorption of the vitamin or its proper metabolism.

### Minerals

Of the sixteen minerals said to be essential to humans, several are of special importance. Sodium, already discussed, is essential for acid-base homeostasis (maintenance of a steady state). Potassium is essential for nerve transmission and its importance is noted in maintaining heart rate regularity. Chloride is essential for water homeostasis and acid-base balance. Low sodium and chloride may result in hypotension, and elevated sodium chloride, in hypertension. Calcium and phosphorus participate in bone metabolism and in nerve transmission. Low serum calcium may result in seizures. Iron and copper are necessary for hemoglobin formation. Copper is also important in protein formation. Iodine is essential for thyroid metabolism. Zinc participates as a cofactor for many of the liver enzymes. Other trace minerals have been suggested as essential elements. Deficiency or excess of any of the minerals may be prevented by appropriate dietary intake unless, like the vitamins, metabolic errors due to genetic abnormalities may relate significantly to ranges of intake needed to avoid deficiency or excess.

### Organs

Any of the organs may participate in metabolic disease. Two are especially prominent, liver and kidney. The liver enzymes participate in protein, carbohydrate, and fat metabolism. Low protein intake may result in edema due to lack of serum albumin. Liver enzymes help maintain glucose homeostasis, and levels of vitamin and fat metabolism. Common metabolic diseases seen with liver failure include albumin deficiency, hematologic disease, hypoglycemia, abnormalities of vitamin D metabolism, abnormalities of fat metabolism, and metabolism of some of the minerals. The liver also is essential for acid-base homeostasis. The liver enzymes are most responsible for detoxification of various chemicals. Liver failure may manifest itself by high serum ammonia levels and ammonia intoxication. Liver scarring (cirrhosis) may be the end result of several insults. Dietary treatment usually includes a low-protein diet that helps avoid ammonia toxicity and may help hepatic healing. Dietary supply of those substances that cannot be produced because of deficient liver metabolism may mitigate deficiencies partially.

The kidney is important in excreting and conserving water. If the body is alkaline, the kidney secretes base; if the body is acidotic, the kidney secretes acid. The kidney regulates secretion of small proteins, amino acids, and glucose. Kidney disease (nephrosis, where body swelling is related to the loss of serum protein, or nephritis, due to inflammation of the kidney) may result in loss of protein. The kidney is active in the metabolism of vitamin D, and deficiency results in abnormalities of bone

and parathyroid metabolism. Kidney disease may result in retention or excess of normal products such as ammonia and urea, or excretion of essential substances such as water. Lack of control of water excretion is renal diabetes insipidus (excessive urine due to kidney abnormality), in contrast to pituitary diabetes insipidus (excessive urine due to pituitary abnormality, resulting in a deficiency of the antidiuretic hormone).

“Inborn errors of metabolism” was a term first used by Sir Archibald Garrod in his Croonian lectures published in 1908. He defined these inborn errors as blocks in metabolic pathways causing genetically determined diseases. He developed the concept that certain diseases of lifelong duration occur because an enzyme governing a single metabolic step is reduced in activity or missing completely, based on his observations of patients with alkaptonuria (urine that turns black upon exposure to light due to the presence of an amino acid breakdown product), albinism (lack of pigment in body tissues, such as hair, due to a lack of enzymes associated with melanin), cystinuria (excessive amounts of the amino acid cystine in urine resembling a form of kidney stone), and pentosuria (abnormal excretion in the urine of pentose, a form of sugar not utilized by humans).

When Garrod diagnosed these patients, most were adults who had been asymptomatic in infancy and childhood. Moreover, he noted that these conditions occurred in families and in many of the families more than one sibling was affected. Parents and other relatives usually were normal. A high incidence of intermarriage was common among affected families.

Following Garrod’s work, others began to look for distinguishing characteristics in related families. For example, in 1934, Folling was working in an institution for the mentally delayed. He tested urine with a chemical, ferric chloride, and found a number of severely retarded children and adults whose urine turned purple upon that reagent’s addition. The cause of the color change was found to be due to phenyl ketone. He and others determined that the phenyl ketone resulted from an error in the metabolism of phenylalanine, an amino acid found in nearly all proteins (Jervis). Many patients were identified with phenylketonuria (PKU) over the next twenty years, but little could be done to prevent mental delays that accompanied this condition.

Though chromatography was invented in Russia at the end of the nineteenth century, it was a technique used mainly for identification of complex substances. In the early 1950s, a number of investigators, particularly Armstrong and co-workers (Armstrong et al.), developed a technique to remove phenylalanine from milk proteins and the ability to diagnose this condition in growing infants became available. A formula with low phenylalanine content was developed at about this time. This formula was prescribed for those diagnosed with PKU and is very similar to the formula that is fed infants with phenylke-

tonuria today. Though the infants with phenylketonuria progressed better than previously and indeed some progressed normally, a large number continued to experience delays in mental development. It was not until the Guthrie test was developed in the mid-1960s (Guthrie) that the diagnosis of phenylketonuria could be made almost at birth. This permitted the diet to be started at a much younger age. Many patients treated from birth progress normally.

Phenylketonuria is due to a disorder of the phenylalanine hydroxylating system. The gene for phenylalanine hydroxylase has been localized. Phenylalanine hydroxylase converts phenylalanine to tyrosine. Excess phenylalanine may be toxic or may convert to other toxic substances, or lack of the product tyrosine may be detrimental. Attempts to treat PKU only with added tyrosine did not completely correct the condition.

Newer instrumentation, gene analysis, and dietary control permit screening of the newborn for a large number of amino acid and other abnormalities; thus, many inborn errors of metabolism can be identified in the newborn and for some of these effective or palliative treatment is instituted. The studies of PKU are a model for many of the errors of amino acid metabolism (Barness and Barness). Each of these inborn errors of metabolism may present as a medical emergency, particularly in the newborn. One group of amino acids, termed branch-chain amino acids because of their chemical structure, improperly may form substances that smell like maple syrup. The disease is called maple syrup urine disease. Its treatment requires adjusting the intake of the branched-chain amino acids. Another group of branched-chain amino acids results in severe acidosis and depression of the bone marrow when inadequately metabolized. Two disorders are relatively common, methylmalonic acidemia and propionic acidemia. Some of these individuals respond to diet manipulation and large doses of vitamin B<sub>12</sub>. Some patients present with an odor of sweaty feet due to a defect in the metabolism of leucine, one branched-chain amino acid. Decreasing dietary protein may ameliorate some of the worst signs of this disease.

One group of infants with amino acid and metabolic error may present with the odor of ammonia. They may become comatose rapidly. They have errors related to the breakdown into urea of one of the five amino acids. They cannot make urea from ammonia. Urea is a benign substance easily excreted in the urine. Affected infants are treated with a low-protein diet and frequently must also be treated with dialysis and ammonia-binding drugs to prevent catastrophic effects to the nervous system (Brusilow et al.).

Fatty acid metabolic disorders are causes of several muscle weakness diseases. Some patients affected by these conditions present with high blood ammonia, heart abnormalities, and coma. Liver disease may be a complication (DeVivo). These are divided according to the size

(length) of the implicated fat. Many of the affected fats normally are excreted conjugated to the amino acid carnitine. Some of the worst effects of these disorders respond to the administration of carnitine and to limited intakes of the implicated fatty acid. Symptoms are aggravated by fasting, and intravenous glucose may be required.

Mason and Turner in 1935 reported a reducing substance identified as galactose in the urine of a number of children who were delayed markedly in development. The substance was found to be galactose and its source was human or cow's milk. Very young infants with the abnormal urinary substance were identified by this test. If allowed to drink milk, these infants frequently had seizures, became jaundiced, and vomited perniciously. They did not grow well. When milk was removed from the diet, they seemed to thrive. They experienced improved growth when they were fed with a soybean-based formula that contained no lactose, the principal sugar found in milks, human and other. Lactose is normally digested to galactose and glucose. The condition is called galactosemia because of the abnormally elevated galactose concentration in the blood.

Since the discovery and treatment of galactosemia, other errors in the metabolism of carbohydrates have been recognized. Some children cannot utilize fructose and develop symptoms similar to those experienced by untreated galactosemics. Children with hereditary fructose intolerance are interesting in that they consume breast milk and infant formulas made with lactose without difficulty. However, when given any food with table sugar, their symptoms become frightening. They quickly learn to avoid sugar or any food containing the fruit sugar, fructose. They grow normally and have wonderfully noncaries teeth. Other diseases of carbohydrate metabolism result in liver, heart, and kidney abnormalities. Some are accompanied by physical abnormalities.

Pauling and colleagues (1949) studied hemoglobin structure and found a specific mutation causing an alteration in the structure of hemoglobin. This led to the discovery of the errors in sickle cell disease. Subsequently, other genetic abnormalities have been identified as responsible for many hereditary anemias.

A common disease in adults is arteriosclerotic heart disease. Genetic abnormalities in cholesterol metabolism are believed to be responsible for atherosclerotic heart disease in some who suffer from this condition. Dietary manipulations and exercise beneficially affect a large percentage of these individuals. Others require drugs. Another group of patients with heart disease demonstrates a defect in metabolism of the amino acid homocystine. Treatment of the elevated homocystine with the same agents used for the treatment of the inborn error homocystinuria may reverse the condition.

Over four hundred inborn errors of metabolism have been diagnosed. Future genetic studies may reveal many

more. Many carbohydrate, amino acid, and fatty acid abnormalities have yielded to effective treatment that must be maintained lifelong—a form of treatment is available for approximately forty to fifty of these conditions, with a similar number having experimental approaches. Some complex abnormalities, particularly those related to body structures and muscle diseases, await gene modification for effective therapy. Although each of the inborn errors, excluding the more common hematologic ones, may occur in only 1 in 4,000 to 1 in 100,000 live births, cumulatively they account for more than 1 in 1,000 of live births. Early diagnosis may prevent severe disabilities in progeny.

**DISGUST.** Some philosophers doubt that there is such an emotion as disgust, yet in spite of the concept's overlap and fuzzy edges, there is a learned discourse about disgust defined as a feeling of revulsion. The prime example is in the context of food. Disgust may cause shock, faintness, even vomiting, or at the least it may dull the appetite. Not only to taste, but also to smell putrefying flesh, to touch excreta or slime, or even to set eyes on an open wound may provoke disgust. As a form of strong rejection, disgust is not the antithesis of desire; its effects are too immediate, even unexpected and uncontrollable, like an instinctive reaction. Why should humans be equipped by nature with this capability?

## Training

A social explanation of disgust focuses on nutrition and the need to train children to avoid known poisons. Babies are taught by their parents' expressions of disgust not to eat noxious things. From the classifying of foods as edible or disgusting, the idea is extended to reprehensible behavior and despised classes of people. The ascription of filthy doings to outsiders accords with theories about the construction of ethnic identity. This approach allows for local differences due to training: some people reject snakes, worms, live grubs, or mud as food, but others relish them. Cannibalism evokes widespread disgust except among cannibals.

The limitation of the social training explanation is that the things commonly regarded as disgusting are not especially harmful. The people who habitually eat what others call disgusting would seem to enjoy as much good health as their critics. Furthermore, if early training in discriminating nutritious food explains disgust, the training is inefficient: it lets pass a lot of poisonous plants, roots, and living organisms.

## Hygiene

The work of Louis Pasteur (1822–1895) and Joseph Lister (1827–1912) on microbial infection gained new relevance to disgust through the revival of Darwinism. An approach via hygiene starts from finding a strong convergence of evidence across the world to show that disgust is a direct response to waste products of the human body, including feces, slime, spittle, pus, mucus, and phlegm, which may carry infection. The same feeling of revulsion is extended to eating similar products of other living organisms and to anything that suggests these body wastes, like snails, slugs, and bugs. Evolutionary biology suggests a genetically inherited disgust mechanism that protects from infectious diseases.

Both the social training argument and the biological argument are open to the objection that the risks of disease from eating sick animals are only probabilities. House flies, mosquitoes, rats, and lice are dangerous to the same degree of probability, but they provoke more annoyance than disgust in those they afflict. Many deadly poisons are not slimy and are quite unlike body wastes, and comparative evidence is missing.

The evolutionary approach invites interesting comparisons. Animals may feel disgust, but the theory of genetic inheritance needs to take account of the exceptions. Many female mammals habitually dispose of afterbirth, smelly, sticky, and slimy as it is, by eating it. Hares and other coprophagous ruminants eat their own feces as part of the normal process of digestion. Sows are known to eat their young. Carnivorous animals do not discriminate between the best cuts and the messy-looking entrails, and some species subsist mainly on carrion.

These two approaches to human disgust conflict, and each side can reproach the other for using selected evi-

dence. The social theory focuses on what the biological theory regards as exceptional, and the biologists focus on the common behavior, discounting the exceptions. Obviously, inherited feelings of revulsion can be overcome by training. Cannibals are trained to surmount disgust at eating human flesh, as are those who enjoy mucus-like turtle soup, slimy innards, snails, live grubs, and sticky buns. If no evidence against the thesis is allowed to count, the argument must come to a standstill.

Both arguments are causal and teleological. Both downgrade the importance of this emotion, taking it to be designed (inefficiently) to achieve a limited objective. Neither explains why the onset of disgust should be so sudden or so violent, liable to rack the whole body. Apart from causal thinking, there is analogy.

## Analogy

A new direction in brain sciences challenges the separation between mind and body (Damasio). In continuous interaction, physical and intellectual energies sift through a succession of images and order them by creating analogies. Instead of looking for specific functions, analogists look for interactions between a system and its parts. Instead of starting with nutrition, analogists start with the body-mind relation and ask how disgust responds to pressures from the cognitive system.

Analogy maps similarities, checks similar patterns for structural consistency. It is a precarious process of reasoning, like trying to hold a pattern steady in a shifting kaleidoscope. The number of possible analogies for any one pattern is infinite, and the pattern always threatens to dissolve. Only repeated enactment entrenches an idea. Entrenchment needs to be fortified by a mechanism of rejection that protects the established pathways from slippage. The digestive organs are the root for making sensations of disgust analogous to other contexts of rejection and for extending disgust to moral or social contexts. Disgust churns the stomach and produces nausea and a cold sweat. Interacting with the cognitive system, its various vivid analogies are a team of watchdogs protesting against changes that, if adopted, would tumble the edifice laboriously constructed by experience.

One of the side effects of disgust may be to reduce the risk of infectious food. Its main function is in the body-mind system, where it limits conceptual slippage. Disgust warns against concepts threatening dangerously to slide between categories.

**DISTRIBUTION OF FOOD.** The distribution of food in the United States can be as short as the distance from a farmer's or a consumer's garden to his or her kitchen table or as long as the journey from vineyards in South Africa to homes in South Dakota. Typically, the distribution of food moves along a complex supply chain that starts with chemical, seed, and feed companies in the agricultural input or agribusiness sector and ends on the consumer's plate at home or in a restaurant. This discussion, using corn as an example, follows food along a few relatively simple food distribution channels to reveal the many paths it takes as it travels from farm to fork.

Corn (maize) is one of the most widely produced grains in the world. In the United States, corn represents more than 40 percent of all grains produced. Four times more bushels of corn than bushels of wheat or soybeans were produced in the year 2000 (U.S. Department of Agriculture, 2001). For decades, university researchers and seed company scientists designed hybrid corn varieties that increase yields and improve quality. In tandem, chemists in public and private laboratories formulated fertilizers and pesticides to further enhance crop yields. In the late twentieth century, many seed and chemical companies merged and redefined themselves as life science companies to reflect advances in biotechnology. The application of genetic science to create new types of seed for corn, soybeans, and other crops touched off a controversy around the world about the safety and efficacy of the new seed supply and the food it produced. The link between the life science companies and consumers leapfrogged over the entire food distribution network as consumers protested this new and relatively untested technology that they perceived as a threat to their health and environment. While the controversy continued, food safety agencies in developed countries struggled with safety and labeling issues surrounding foods made from genetically modified ingredients. Life science companies and other agribusiness firms meanwhile continued to supply farmers with the seed, chemicals, and equipment needed to produce their chosen agricultural commodity, in this case, corn.

Once a farmer harvests the corn crop for the year, distribution of the raw commodity begins. At least two basic types of corn are produced, sweet corn for direct food consumption and field corn for food ingredients and animal feed. Each type has numerous varieties, brands, colors, and end uses. A small portion of fresh sweet corn

might be sold at a roadside stand or in a farmers' market. In smaller communities, a farmer may deliver some sweet corn directly to a local grocery store or restaurant. Most of the new sweet corn crop is sold to commercial food processors, where it is canned or frozen.

Corn designed to be used as seed, animal feed, ingredients for food, or industrial products is sold to a local grain elevator. The choice for the farmer is to store the field corn on the farm and wait for the best market price over the course of the next year or to sell it to a grain elevator immediately. Some grain elevators are independent businesses, and some are owned by large food or feed companies that collect grain from across the land. At the elevator, corn is usually mixed and matched to achieve the quality demanded by the next buyer. Occasionally an elevator may handle only one type of corn grown by a few farmers who have contracted with a large food or feed company to supply a particular quality and quantity of grain. In this case, the identity of each type of corn is preserved. With bioengineered corn and other new varieties, the issue of identity preservation became a major issue. Traditional farming methods and grain elevator operations were incapable of keeping all varieties of corn separated and identified throughout the food distribution chain.

At the beginning of the twenty-first century, however, the development of technology and methods to preserve the identity and origins of all types of food was under great pressure to succeed quickly. Tagging and following foods from their origins to the point of retail sale was considered important for consumer choice and as a way for superior foods to capture higher market prices. It would also permit foods proven unsafe or undesirable to be traced back to their sources.

After leaving the grain elevator, about 20 percent of the corn was exported to a foreign country in 2000 (U.S. Department of Agriculture, 2001). The rest was sent to a feed mill or to a food processing or manufacturing plant. Some went to industrial plants that produce products like ethanol or plastics. At a feed mill, corn is further mixed with other grains and additives on its way to being fed to animals, such as hogs or chickens, many of which are later slaughtered for food. In fact, the bulk of the corn produced is used as animal feed. Corn used for human food usually goes directly to a food processing plant that specializes in producing basic ingredients, such as corn oil, starch, or flour. These ingredients are sold to food manufacturers, who use them in manufactured foods for consumers to eat. More complex food products, like taco shells, corn flakes, or corn bread, generally use ingredients purchased from food processors.

At the food manufacturer, major research and development departments create and test the safety and efficacy of food ingredients, flavors, and additives. They also experiment with new recipes, new packaging, and new ways to use corn in foods. Much attention is paid to

the image of the food, its safety, its shelf life, its nutrition, and labeling. Several hundred new corn products are introduced to grocery shelves each year in an attempt to meet consumers' preferences and to capture part of their food dollars. This is also true for foods from other raw commodities, like rice, milk, eggs, and wheat. The average annual number of new food products introduced during the 1990s was 12,700, peaking in 1995 at 16,863 (Food Industry Institute, 1999; Food Industry Institute, 2000). Less than 5 percent of these new products were still on the grocery store shelves two years later.

Food products designed for the food service distribution channel also undergo extensive development and market research before going to market. These foods need less elaborate packaging and labeling and less advertising. They are designed to solve problems in a restaurant kitchen, problems of consistency and fail-safe cooking. Food service firms, such as quick service chains, purchase large and predictable quantities of food, often tailored to their specific needs. The distribution channel to food service firms was growing while the grocery channel was stable to declining at the end of the twentieth century. In any case, by the time the food product containing corn leaves the food manufacturer's warehouse, corn represents less than 20 percent of the value of the product. By the time a consumer purchases that product, corn represents less than 5 percent of the value (Elitzak, 2000).

### The Grocery Channel

When a consumer food product leaves the manufacturer's plant for a grocery store, it has three channels through which it may travel. One is through a wholesaler's warehouse, where it is stored until a grocery store orders it. A traditional way of doing business is for the manufacturer to discount large quantities of freshly made food products to entice a wholesaler to "forward buy" the product. The wholesaler then stores it, marks it up, and sells it to a grocery store, making a profit on the difference in price. The costs of holding large inventories of food drove the industry to find more efficient ways to distribute food. With low inflation and fierce price competition at retail stores, wholesalers could not mark up their products enough to make reasonable profits. The quest to decrease distribution costs led to a consolidation of wholesale and retail firms and to the adoption of new information technologies.

Trade associations of retail food companies and manufacturers, such as the Food Marketing Institute (FMI) and Grocery Manufacturers of America (GMA), have long led the industry in adopting information technology. In the early 1970s, with the high cost of labor amplified by price inflation, the grocery store industry saw great potential in automating pricing activities. The Ad Hoc Committee on Universal Product Codes was established with representatives from major retailer and product manufacturing associations to develop a set of standards for identifying products that both the retailers

### FOOD DISTRIBUTION SYSTEMS IN COUNTRIES OTHER THAN UNITED STATES

The food distribution system used in the United States is similar to that used in most of the westernized world (Europe, Australia, New Zealand, Japan). It requires good transportation and telecommunication systems and a modern food processing/manufacturing sector. In the United Kingdom there are few broad-line wholesalers, since the retail sector is more consolidated and handles its own distribution through tighter relationships with food manufacturers and producers. In other countries, large supermarket chains and chain restaurants receive food in much the same way as those in the United States, but there are a larger number of small retailers that procure their food directly from farmers or through third-party specialty wholesalers. In lower-income and emerging economies, the distribution of food is developing along the lines of the system used in the United States. Some level of household income and urbanization must emerge before supermarkets will become part of the retail food scene, and roads and communications need to be in place before a third-party distribution system can develop. For example, in China in 2002, Western-owned food manufacturers provided their own delivery to large supermarkets like Wal-Mart in the absence of a wholesale sector in the supply chain.

Globally, a few very large retailers are appearing around the world; their buying power tends to drive the delivery system and the types of food being purchased for retail sale. As these large retailers become more prevalent, the delivery system gets more consolidated, more responsive to consumers, and less open to small producers and farmers.

and manufacturers could agree upon. Two years later the committee decided to adopt a ten-digit Universal Product Code (UPC) as its standard (Kinsey, 2000). The ubiquitous bar codes were born, and in 1974 a supermarket in Troy, Ohio, became the first to implement scanning. The first grocery store chain to implement scanning chainwide (Giant Foods) did not do so until 1980 (Walsh, 1993). By 2000 virtually every supermarket used scanners, though they were not widely adopted in convenience stores. At the time, scanners were still not widely used in the food service sector due in part to a lack of standardized products and packages for food service buyers.

Using the information in banks of scanner data can give retailers valuable information with which to forecast sales, design customer loyalty programs, and con-

trol inventory. When Wal-Mart appeared as a major competitor with the most sophisticated information and distribution system yet known to retailers, it became obvious that those in the retail food industry would have to learn how to do business in the same fashion. In 1992 an industrywide program called Efficient Consumer Response (ECR) was developed to solicit conversion to electronic technologies and sharing of retail data with suppliers. By 1999 this program was declared dead by industry leaders partly because it had outlived its usefulness, partly because only the largest chains were able to invest in the technology and talent that would make it work, and partly because many ECR activities had already been adopted under separate names, such as category management and activity-based costing. By the end of the twentieth century, however, developing systems that would allow business-to-business, electronic-commerce methods of sharing information about final sales at retail stores with wholesalers and manufacturers became an industry goal. With real time sales data, manufacturers could adjust production and shipment of new products to match the flow of sales and accomplish continuous replenishment and lower distribution costs.

Wholesalers were vulnerable in this new distribution system since retailers could bypass them by using their own distribution centers. To keep their retail customers, wholesalers developed new services, like helping stores with their billing, merchandising, inventory management, and a number of other tasks. Wholesalers make it possible for small stores to carry a large number of items even though they may sell only a few of some specialty items each year. Some wholesalers specialize in particular types of foods, such as organic food, imported food, or fresh produce. Those who handle the whole line of groceries are called broad line wholesalers. Shipping food from manufacturers to wholesalers and from wholesalers to retail stores involves a large number of trucks, many of which need to be refrigerated to keep cold and frozen foods at a consistent and safe temperature. One of the

difficulties in transporting food is the attention that must be given to temperature and the time the product will last before its quality or safety deteriorates.

The third party, broad-line wholesaler channel declined in size with the rise of large grocery chains like Wal-Mart and Kroger. Large chains have their own distribution centers in which to aggregate, store, and ship foods to their own stores. In this case, manufacturers sell food products directly to supermarket chain's distribution centers. In 2000, forty-five of the largest fifty supermarket chains in the United States were self-distributing chains.

A third channel by which food reaches grocery stores is called "direct store delivery." In this case, manufacturers have their own delivery trucks and sales representatives who deliver products to individual stores, stock the shelves, remove out-of-date products, and promote their products in stores. Most beverages and salty snacks are delivered directly to stores by manufacturers' trucks and personnel. At the beginning of the twenty-first century, each of the three distribution channels carried roughly one-third of the volume of food to grocery stores.

In 1999 about 127,000 grocery stores operated in the United States, of which 25 percent were supermarkets and 45 percent were convenience stores. At that time a supermarket was defined as a retail store that carries a full line of groceries, meat, milk, and produce and has over \$2 million in sales per year. Supermarkets captured 77 percent of all retail food sales, while convenience stores had only 6 percent. About 70 percent of the food eaten was purchased at some type of grocery store, where consumers spent about 53 percent of their food dollars in the late 1990s (Carlson et al., 1998).

With the advent of large and efficient supermarket chains, the propensity for grocery chains to build long-term relationships directly with manufacturers increased. The sharing of sales forecasts based on large volumes of computerized sales data facilitated these relationships. Knowledge about customers' preferences and shopping habits gained through analysis of sales data made it possible for large retail chains to negotiate for bargain prices as they placed orders that matched what they needed, when they needed it. In some cases this eliminated the need for "slotting fees," the price retailers charge manufacturers to place new products on their shelves. Computerized scanner data and Internet communications made it possible to integrate the supply chain between manufacturers and food retailers and to streamline the inventory in distribution centers. Sharing sales data and mutual tracking and analysis made it possible to substitute information for inventory, cutting costs in the distribution channel. It became possible to match deliveries more closely to the time of sales, converting the food distribution channels into a semblance of just-in-time delivery. The adoption of business-to-business e-commerce, a new way to do business for retail food stores and their suppli-

ers, focused mostly on ways to save labor costs and to speed up ordering, delivery, and invoicing. The goal was to move products through the system as freshly and as quickly as possible.

### Food Service Channel

The food that goes to food service establishments (restaurants, fast-food places, cafeterias) goes through a separate distribution channel. Here again are broad-line wholesalers, specialty wholesalers, and some distribution companies dedicated to a large retail chain like McDonald's or Burger King. This complex distribution channel links over 740,000 food service locations with more than 2,600 distributors. Consolidation among broad-line wholesalers was rapid around the beginning of the twenty-first century. They distributed about half of the food to various food service places (Friddle et al., 2001). Over 30 percent of the food eaten in the United States went through the food service channel. Consumers spent almost half of their food dollars in food service places.

Food service is divided into commercial and non-commercial enterprises. The noncommercial segment comprises about 10 percent of the food service sector and includes schools, hospitals, prisons, and the military. The commercial food service sector includes bars and restaurants, travel and leisure, vending machines, and take-out (ready-to-eat) food from grocery stores and various types of restaurants. Restaurants and bars comprise about 62 percent of all food service sales and are further defined by the type of service they provide. Quick service (fast food) restaurants captured thirty-three percent of consumer expenditures at food service places, while full-service restaurants captured 28 percent. Full-service restaurants are further classified by whether the average size of the check is over or under \$10. The lower-priced full-service restaurants were growing in importance as a proportion of food service sales in the late 1990s. These restaurants also represented the largest consolidation of individual units into national and international chains.

### Summary

Food is distributed from retailers to consumers primarily through grocery stores or take-out food places. For the most part, consumers shop and take home their own food. Home delivered food experienced a resurgence with the rise of Internet food companies in the 1990s and beyond. Online shopping and home delivery made up less than 1 percent of all food purchased for home consumption but was a persistent phenomenon in some neighborhoods. Food distributed through food service became ubiquitous by the end of the twentieth century. Food and beverages could be purchased from vending machines, street-side stands, drive-through eateries, office cafeterias, shopping mall food courts, and home delivery.

When consumers finally eat the food that has traveled all the way down a long supply chain, few think about the corn delivered to a grain elevator or the canning plant

months earlier. Corn oil is in their salad dressing, their soft drink sweetener, and their taco shell, but it is largely taken for granted. It is assumed that it is fit to eat, nutritious, and safe. Few think about the hundreds of people involved in producing and transporting the final food product or the plethora of food regulatory agencies that license, monitor, and inspect the process. Food distribution is a long and complicated journey, but somehow an army of scientists, truck drivers, forklift operators, computer specialists, government scientists and inspectors, and many others make the system work.

**DIVISION OF LABOR.** Division of labor, the parceling out of work based on various categories of identity, is understood commonly as a division made on the basis of gender. Indeed, food production, preparation, and even consumption are often differentiated on the basis of gender: men do some tasks and women do others. For example, cooking is widely recognized as an essentially female task (Murdock and Provost, p. 208). However, division of labor can apply to class, ethnicity, and age as well, and these categories also intersect with how people produce, prepare, and consume food.

### Food Production

The division of labor begins when food production begins, which is a pattern rooted in the history of humanity.

The earliest humans tended to divide their work by category, where men hunted and fished and women gathered vegetable foods (fruits, vegetables, grains, and nuts). Among foraging societies, women still take on the greater portion of food-preparation tasks, such as grinding, pounding, boiling, and otherwise processing gathered and hunted foods into edible meals. For the few societies that still procure their food in the hunting-and-gathering strategy, a large percentage of the diet is made up of non-meat foods, with meat functioning as a much-desired and prized treat (Lee, pp. 256–258).

As societies adopted farming as a means of food production, dividing food production by gender persisted, yet much of this division was based on cultural understandings of gender rather than a physical advantage on the part of men or women. For example, among the Maring of New Guinea, numerous agricultural tasks are divided on the basis of gender: men and women together clear gardens, but only men fell trees. Both men and women plant crops, but weeding is a primary female occupation. At harvest time, men harvest above-ground crops and women harvest below-ground crops (Rappaport, pp. 38–40, 43). These are categories based on cultural understandings, similar to how grilling and barbecuing are identified as male tasks in many Western societies.

An extreme case of agricultural specialization is found in much of sub-Saharan Africa, where subsistence agriculture is a predominantly, sometimes exclusively, female task. Agricultural economist Ester Boserup notes that in sub-Saharan cultures, the shift to a more urbanized society often reduces women's status, for although rural farm women may not be socially equal to their husbands, their work on farms is recognized and valued. A shift into a more "Westernized" work pattern can eliminate what power such women do have (pp. 53–63). However, agricultural work patterns vary widely. In societies where plow agriculture is common, women are often likely to process food in the home, while the actual farm labor falls to men; yet even in those societies, women may weed and harvest or keep kitchen gardens. In the United States, women's farm participation varies from negligible to great. The publication *Marketing to Women* notes that although the number of women farmers in the United States is on the rise, women tend to own the smallest farms. At the same time, women are far more likely to own their farms: fully 80 percent of women farmers are farm owners, in contrast to the 58 percent of male farmers who own their farms.

### Preparing Foods

Food preparation, particularly that which occurs in the home and family, is most strongly associated with women and women's work. This is a pattern that has been documented widely. Journalist Laura Shapiro and food writer Ruth Reichl outline the history of this development in the United States in *Perfection Salad*, their account of the

"domestic science" movement. As a result of this movement, women's work came to be viewed as professional, and cooking and other domestic activities were elevated to a woman's highest calling. (See also Cowan. Numerous works from a range of disciplines document this pattern. Among them are works by Sherrie A. Inness and the U.S. sociologist Arlie Hochschild.)

Similar patterns have emerged in other societies, although the underlying cultural ideals may differ. Anne Allison describes the great attention that Japanese mothers give to the preparation of their preschool children's boxed lunches. Young children attend preschool from three to six years of age, where they bring elaborately prepared lunches with them. Mothers organize other family meals around lunch preparation and spend as much as forty-five minutes each morning preparing lunch for their preschoolers. Men never prepare such lunches, and no adult that Allison interviewed could ever recall their father preparing a lunch. Indeed, the elaborate and beautifully presented lunch reflects well on the mother and signals her devotion to her children in the eyes of other mothers and of the preschool staff.

The association of women and domestic food preparation is sufficiently strong that men's cooking requires explanation. In some societies, men prepare special or ritual meals. The ethnographic film *The Feast*, by Timothy Asch, shows Yanomamo men preparing and eating a ritual meal, which is unusual in this strongly patriarchal Amazonian society.

### Other Types of Divisions

However, gender is not the only way that labor is divided. This is true for food preparation, as it is for many other types of labor. Class or rank is a major category of division. For example, among the affluent in society, in modern times as well as in the past, servants often prepare food for the household. Also, certain kinds of foods might only be prepared or consumed by people of specific social classes. Archaeologist Christine Hastorf's work in Peru traced the preparation and consumption of corn, in the form of corn beer, through the pre-Incan and Incan periods. Using a sophisticated array of techniques, Hastorf compared the presence of corn pollens among different house sites and throughout neighborhoods. Over time, the presence of pollen, generally found in the patios and yards where women prepared food, was concentrated in the house sites of elite classes. The preparation of corn slowly shifted from most women to elite women. Further comparisons of this type showed that over the same period of time, women's consumption of corn decreased overall, while men's consumption increased in elite neighborhoods. Hastorf hypothesized that with the rise of the Incan Empire, elite women became increasingly specialized corn-beer producers and elite men became the beer's main consumers.

Perhaps the most striking change in U.S. food preparation is that most people do not prepare their own food.

An increasing number of people pay to eat food that is prepared elsewhere, whether they pick up burgers at a drive-through restaurant, order pizza, or buy prepared meals in markets. This pattern has been noted for much of the past twenty years (see Gonzales) and continues to intensify.

**DURIAN.** The durian is a tropical fruit encased in a spherical or ovoid spiny hard shell, which can be quite large—a single unhusked durian can be the size of a football. Within the shell are five or six segments of golden or cream-colored custardy pulp, the flavor of which is reputed to be so delectable that it is commonly known in

#### ORIGIN OF THE DURIAN

In Africa, on the Indian Ocean island of Zanzibar, there grows a stand of durian trees near the site of the former slave market. Two stories account for its origin. One is that Arabs had brought back the durian from Indonesian explorations in the eighteenth century. Another story is that the British colonial governor of the 1850s decided to plant every tropical fruit in this garden, but it was the durian that took root and predominated. The durian is beloved by the Zanzibari (although mainland Tanzanians find it repulsive).

Southeast Asia as the "king of fruits." But perhaps even more notable about the durian than its taste is its remarkably foul odor.

#### Nasal Nightmare or Palate Pleasure?

Sir Stanford Raffles, doughty founder of modern Singapore, proudly told friends in 1819 that whenever he caught a whiff of the fruit, he would "hold his nose and run in the opposite direction." The distinguished nineteenth-century naturalist Henri Mouhot found it relatively easy to trudge boldly through the Cambodian jungles when he discovered Angkor Wat, but give him a durian, and his delicate French olfactory senses would be offended to a point of desperation. "On first tasting it," he reported in his diaries, "I thought it like the flesh of some animal in a state of putrefaction."

What makes the durian both hostile and iconic is the thick rind of the fruit. As cleavers chop through it, an aroma propels upward, inspiring unsavory images: old unwashed socks, subway bathrooms, carrion in custard, fetid cheese. How nearly unimaginable that the taste of this source of nasal distress could evoke such imaginative and savory descriptions as "a bouquet of wild honey with a hint of smoked oak" or "bittersweet butterscotch." But such is indeed its reputation. The flavors of durian varieties range from nutty (the common Thai *chunee*, or "gibbon" durian) to butter-almond (the *maung thong*, or "golden pillow" durian) to crème brûlée (the newly crowned king of flavors, *daan yao*, or "long-stem" durian).

#### A Cultural Identity

While no festival is devoted to the durian, its Thai devotees crowd the ten-cent ferries from Bangkok to the province of Nonthaburi, where the finest durian grow, from April through July. There, along the port, the laughter of appreciation, the sounds of thick spiky rinds being chopped open, and a pervasively acrid aroma float and mingle together over the Chao Phraya River.

## DEFENDING THE DURIAN

It has been said that Asians enjoy pricking the somewhat constrained food preferences of foreigners by offering them durian and watching the knee-jerk negative reactions. Usually the results are harmless and amusing, but sometimes when the untrained nose meets the noisome fruit, the culture clash can be more antagonistic than amicable. Some years ago in Thailand, where durian is a matter of national pride, a Thai lady from Bangkok's red-light district was accused of slashing an American's face with the sharp spines of the durian. Her excuse was that she had been innocently dining on the durian in the back of a bar, when the American stormed in to castigate the revolting smell coming from the fruit. What choice did this woman have but to claim durian rights and defend the fruit? The Thai magistrate, a patriotic durian eater himself, found the assault was, alas, criminal. But in deference to the noble durian, he penalized the woman the equivalent of a mere five dollars and, as if to underscore the virtue of her actions, paid the fine himself.

In 2000, Hong Kong filmmaker Fruit Chan wrote and directed *Durian Durian*, a movie that explores the lower classes of Hong Kong's steamy tenement district of Mongkok. The two durian in the title represent the story's two vulgar, ambitious women, who, like durian the fruit, are repulsive to outsiders but charming to their own society. And, like the Malays (who say "when the durian falls, the sarong falls"), the Chinese consider durian an aphrodisiac.

## Botanical Profile

The durian (which the French dub "cheese-vending tree") is a member of the bombax family (Bombacaceae), a diverse family of trees that includes the thick-trunked baobabs of Africa and Australia, the fast-growing balsas of tropical America, and the kapok-yielding ceibas of Africa and tropical America. The durian (specifically *Durio zibenthus*) probably originated in Borneo, and today its numerous varieties are cultivated primarily in Malaysia, Thailand, Indonesia, and the Philippines. The durian tree, resembling the American elm, is of majestic height, reaching up to 120 feet. For its first five years, the trees are delicate, requiring humid climate and protection from fruit borers and leaf-cutters. From its fifth year, it begins to bear approximately forty fruit; by the tenth year, up to 200 fruits. Each of the spiky green fruits can weigh up to eight pounds, so during the harvesting season, it is most inadvisable to walk under a tree, since,

upon beginning to ripen, the fruits fall from their lofty branches.

Humans are by no means the only eager consumers of the durian. According to a Thai maxim, "the first to note the malodor is the elephant, which shakes the tree to bring down the fruit. After the elephant noses open the fruit with its tusks, the tiger fights the elephant for the fruit. Rhinoceros, wild pig, deer, tapir, monkey, beetle, and ant follow the tiger. The human must be very quick to get the durian."

## The Marketplace

Assuming no frugivorous animals have broken the husks, durians are trucked to market, where the durian buyers make their selections. As an iconic fruit, social status is important here, and only the most desperately poor will be satisfied with the lowly *chunee*. Others will look for the more desirable—and more costly—*maung thong* pile.

Which are the best in the pile? Some Western writers claim that the odor is the hallmark of a good durian, but in fact the husk is so tough that only a scintilla of the smell can pierce through the young fruit, which takes two or three days to ripen fully after falling. Those experienced in the durian trade know that it is sound, not scent, that identifies an acceptable specimen. The durian merchant will hold the durian by the stem, while the buyer lightly taps on the top of the fruit with a hand or (preferably) a carved teakwood stick. The other hand is held behind the buyer's ear to catch the resonance of the tap, much as a conductor will catch the timbre of violins in an empty auditorium. If the sound from the durian is a thud, the fruit is touching the husk and not ripe enough. If the sound is hollow, then it is overripe and mushy. Something between a thud and hollow, therefore, is ideal.

The export market for durian is limited, since no airline allows the transport of fresh durian (even in the luggage compartment, the aroma can seep up to within sniffing range of the passengers). Nonetheless, the de-

mand for this “king of fruits” among Western consumers is on an increase. To be sure, canned durian brought some 30 million dollars in exports in the year 2000, with the United States comprising one-third of this market.

### **Preparation and Consumption of the Durian**

Slicing the durian open with a sharp cleaver offers a dissonance of reactions. The smell is indeed fetid, but the compartments within contain generous servings of pulp that is solid (but not dry) and creamy (but not milky). The fruit can be consumed by hand or spoon, extracting the chestnut-sized seeds embedded in the pulp. Fresh durian pulp can be wrapped in foil and stored in a freezer but inevitably loses its delicate taste.

Different cultures use the durian in a variety of ways. In Borneo, the indigenous Iban boil or salt unripe durian, using it as chutney on their sticky rice. In mainland Malaysia, the seeds are roasted or fried and eaten like popcorn. In Sri Lanka, where durian grows wild, farmers will take durian pulp and mix it with curdled buffalo milk, sugar, and sometimes cinnamon or cloves.

Other variations, like durian jam and candy, are made for those who want a taste of durian without the effort of the aroma. Among the most popular recipes is durian ice cream: chunks of the fresh fruit are blended into a puree, mixed with pineapple or orange syrup, and poured

onto the ice cream. Fresh durian is also used for a durian “cake.” This Malaysian treat is made with durian pulp and sugar, slowly boiled together and wrapped in palm leaves. These cakes keep up to one year in the freezer. Incidentally, consuming durian, in any form, with liquor is strictly avoided. It is a long-standing belief that fermenting the fruit in the stomach with alcohol can be lethal.

**EASTER.** Easter, the Christian festival commemorating the resurrection of Christ, was the earliest feast day decided upon by the ancient Christian Church. Like its Jewish predecessor Passover, it is a movable feast, based on the lunar calendar rather than falling on the same Sunday every year.

The complicated dating for Easter was set in 325 at the Council of Nicaea, which scheduled the festival to be celebrated on the first Sunday following the full moon occurring next after the vernal equinox (about March 21); however, if the full moon occurs on a Sunday, Easter will be celebrated the following Sunday. Hence, the date of Easter can fluctuate between March 22 and April 25. Because the Western churches (Catholic and Protestant) now follow the Gregorian calendar, the Eastern churches, which follow the unrevised Julian calendar, celebrate Easter (and other Church holidays) on different dates. In the Orthodox Churches, Easter marks the beginning of the ecclesiastical year.

Like many other Christian feasts, the celebration of Easter contains a number of originally pagan or folk-religious elements tolerated by the Church. Among these are customs associated with the Easter egg, Easter breads and other special holiday foods, and the European concept of the Easter hare, or, in America, of the Easter rabbit, which brings baskets of candies and colored eggs during the night.

The pagan roots of Easter involve the spring festivals of pre-Christian Europe and the Near East, which celebrate the rebirth of vegetation, welcoming the growing light as the sun becomes more powerful in its course toward summer. It is significant that in England and Germany the Church accepted the name of the pagan goddess "Easter" (Anglo-Saxon *Eostra*—her name has several spellings) for this new Christian holiday. In Mediterranean Europe (Italy, Spain, and France), Christianity adopted *pascha*, a word derivative of Passover, from which comes the adjective "paschal" for things pertaining to Easter, such as the Paschal Lamb.

Aside from the fact that Easter Sunday officially ended the long fast of Lent, one of the most distinctive food elements of the Easter celebration is the Easter egg. In earlier times, Easter eggs were much more a part of

the formal culture than they are in America today, where individual families determine the range of the custom. In the European village context, Easter eggs were once used as part of one's tithe to the landlord, or given as festive (and expected) gifts to the village pastor, the schoolmaster, the sexton and bell-ringer, the parish gravedigger, and even the village shepherd. Of course, they were hospitably presented to visitors, bestowed as favors upon servants, and, above all, given to children. Courting couples exchanged them as tokens of love, and godparents usually regaled their godchildren with gifts of decorated eggs.

The Easter rabbit (Easter hare in Europe) is not documented before the seventeenth century. While the Easter hare is the major egg supplier in European Easter celebration, there were other runners-up in the form of egg birds, Easter hens, cranes, storks, even foxes and other creatures. With its late origin, scholars are still debating the reasons for the association of the rabbit with Easter custom and lore. It is generally thought that, like the Christmas tree—and the recent development of Easter egg trees—the custom first emerged in the cities, then filtered down into the country villages. Among the theories of the origin of the Easter rabbit belief, the most plausible (although still not without difficulties) is that it may be connected in some way with the so-called March Hare of folktale. The Easter rabbit was believed to actually lay the eggs; hence, children went to elaborate lengths to build attractive "nests" for the elusive egg layer, who was summoned by whistling or by saying a charm.

The elaborate decoration of Easter eggs became a major form of home-produced folk art both in Europe and America. Among the Pennsylvania Dutch, who produced an elaborate Easter culture, eggs are dyed with onion skins, producing a rich reddish-brown color, or with other natural dyes. These eggs are then scratch-carved with designs, dates, names, or even religious verses, or elaborately decorated by winding the pith of a reed around the egg to create patterns. The Pennsylvania Dutch also make Easter birds out of large goose or duck eggs, furnishing them with wings, beaks, and tails. These are hung from the ceilings of farmhouse kitchens as festive seasonal decoration.

French ceramic mold for baking Easter bread in the shape of a Paschal lamb, circa 1850. ROUGHWOOD COLLECTION. PHOTO CHEW & COMPANY.

In areas of Canada and the United States where Russian and Ukrainian Orthodox Christians as well as Poles and other Eastern Europeans settled, unusual methods of egg decoration are found. Such Easter eggs are generally referred to as *pysanka* (plural *pysanky*). In Eastern Europe, egg decoration is an ancient folk craft treasured in families and passed down from generation to generation. In Czarist Russia, this craft was elevated to such a degree that it was even imitated by such famous jewelers as Fabergé. Whether created with gold leaf and sapphires or just homemade dyes, the designs involve a variety of standard motifs—geometrical, animal, and floral. The geometrical motifs are probably the oldest, and range from simple horizontal and vertical lines to sectionalize the egg to sun symbols like the tripod, or to the “endless line” forms. Some of the most complex patterns incorporate stars and rosettes. Animal and bird designs are the rarest; the reindeer is said to symbolize wealth and prosperity, while the hen, or the feet of a hen, symbolizes fertility and fulfillment of wishes. Butterflies, fish, and horses are also occasionally included in the design repertoire. From the plant world, pine trees are drawn to symbolize eternal youth and health. Many of the Slavic methods of decoration are similar to those used by the Pennsylvania Dutch, but the range of motifs is different, the colors more striking, and the designs richly elaborate. Background colors are often red or black, although green and yellow are also popular, but multicolored designs seem to be the most popular.

In the family and community of all the various Christian denominations, Easter Sunday has always been a day of joyous celebration. In the Middle Ages it was often

chosen as the day to crown kings since Easter feasting was, and remains, quite elaborate, especially in the Orthodox tradition. Since the day marked the official end to forty days of the Lenten fast, many special foods were prepared to mark the occasion. Easter breads have been researched widely and form a huge genre of ornamental foods made especially for this feast. Among the Greeks, lung soup is very much associated with Easter cookery, while in America baked ham seems to be one of the most common features of the Easter dinner. Many games were played with Easter eggs prior to or following Easter dinner, such as egg picking, where the player forfeits his or her egg if it cracks during the picking, egg eating contests, and egg rolling contests. In Europe and in parts of colonial America, Easter was often extended into a two-day celebration, with feasting, gaming, and other secular entertainments continued into Easter Monday.

Easter has undergone further evolution in more modern times, especially since the latter half of the nineteenth century. The confectionery trade began to commercialize Easter during the 1870s, with the introduction of an entirely new line of sweets employing Easter themes. Chocolatiers in particular discovered that candies once only sold as luxury foods for Christmas could become just as lucrative when transformed into rabbits and similar gift items. Today Easter is one of the most important seasons for selling confectionery, from chocolate bunnies, marshmallow chicks, and jelly beans, to music box coconut eggs, spun sugar tulips, and edible crucifixes filled with brandied fruit.

The most concise reporting of Easter customs in Europe occurred at a symposium on Easter organized by Robert Wildhaber of Switzerland. Wildhaber edited the papers and published them in 1957 in the *Schweizerisches Archiv für Volkskunde*. The papers cover Eastertide as cel-

ebred in Switzerland, Germany, Austria, France (especially Alsace), Slovenia, the Czech Republic, Slovakia, Poland, Hungary, Rumania, Bulgaria, and Greece. The majority of the contributions deal with Easter eggs, their history, function, decoration, role in folk medicine, and in riddles. Several contributions treat Easter foods, especially Easter breads and other baked goods. Venetia Newall's *An Egg at Easter* (1971) is the most expert introduction in English to the history of the Easter egg and its place in ecclesiastical and folk culture.

**EATING: ANATOMY AND PHYSIOLOGY OF EATING.** "Eating is the action of taking solid foods in the mouth in order to nourish oneself: this action is carried out by insertion [of the foodstuff] in the mouth, followed by mastication, swallowing, and digestion." This is the definition of "eating" proposed by Diderot in his famous *Encyclopedia*. He goes on to say that eating is specifically not the ingestion of non-food substances such as clay, chalk, stones, and charcoal, but only the ingestion of materials that can be conceived of as foods proper for nourishment. As a result, they also exclude such potential foodstuffs as blood and urine. In the present article, we follow the lead of our predecessor in adopting this definition.

Taking in nourishment is necessary for survival, and this usually involves eating. The following chapter pro-

vides an overview of the anatomy and physiology of eating, including the major nutritional processes that take place during digestion.

Eating can be divided into the following processes: eating proper, or ingestion, whereby food enters into the body; and digestion, the process through which nutrients from food are extracted in the gastrointestinal tract. Digestion is followed by absorption, the process through which nutrients are passed through into the blood stream; and by excretion, through which indigestible and unabsorbable products from food are eliminated.

#### Anatomy

The ability to eat and digest food hinges on an intricate, complex, and coordinated system known as the digestive system, all under control both of the central nervous system (brain and spinal cord) and of digestive system's own intrinsic nervous system, which is sometimes called the body's "second brain." The digestive system comprises two main groups of organs: the organs of the alimentary canal, also known as the gastrointestinal (GI) tract, and the accessory digestive organs.

The GI tract is a continuous tube that runs from the mouth to the anus. The organs of the gastrointestinal tract include the mouth, pharynx, esophagus, stomach, small intestine (consisting of duodenum, jejunum, and ileum), and large intestine. It is within the GI tract that food is chewed or masticated, then broken down into still smaller fragments, and absorbed into the blood.

The accessory organs of the digestive system are the teeth, tongue, salivary glands, liver, gallbladder, and pancreas. The teeth and tongue allow for chewing, tasting, and rasping of food. The other accessory organs of the digestive system produce secretions that aid in digestion. In embryonic life, these organs develop as outpouchings from the primitive GI tract, and their secretions travel into the GI tract via ducts.

In order to understand eating and digestion, it is important to imagine what the body needs to do when you think about food, eat food, swallow food, when food lands in your stomach, and when food makes it way through the small and large intestines. The digestive system is designed to prepare the body for eating and digestion before the first piece of food passes our lips. Once food is ingested, this system is designed to efficiently extract and absorb nutrients while it rids the body of waste products.

#### Preparation for Eating

In order to understand how the body prepares for eating, it is important to realize that eating and digestion require that our body maximizes blood flow to the digestive organs, in order to both supply oxygen and energy to these organs, and to carry away the nutrients that have been absorbed.

Blood flow to the digestive system is controlled primarily by the autonomic nervous system (ANS). The

ANS has two anatomically and functionally different subdivisions, the sympathetic nervous system and the parasympathetic nervous system. The sympathetic nervous system is designed to stimulate the body to prepare for and engage in activities and behaviors that are highly arousing, for example, “fight or flight reactions,” while the parasympathetic nervous system is designed to prepare the body to engage in activities and behaviors that are relaxing.

Eating and digestion require the body to be relaxed, to allow for blood to be shunted away from the muscles to the digestive system. In fact, from an evolutionary point of view, the process of eating requires us to stand still or (preferably) to sit or lie down, and concentrate on taking apart the food item and ingesting it, rather than running around. Thus the processes involved in eating are antithetical to moving about, either to get somewhere or to escape danger.

As a consequence of this organization, the body cannot appropriately engage in relaxing behaviors if the sympathetic nervous system is activated, and it cannot engage in arousing behaviors if the parasympathetic nervous system is activated. In other words, if you feel stressed, or you are engaged in physical activity, or you must flee from danger, you will not be able to eat and digest food, and vice versa.

Both mental stress and aerobic exercise involve activation of the sympathetic nervous system. You may have noticed that if you try to eat while you have been highly stressed, or while you are “on the go,” or after you have exercised aerobically, your mouth may have been dry, making it difficult to moisten, taste, and swallow food. You may have also experienced stomach cramping and pain upon ingesting food. These responses occur because your sympathetic nervous system is stimulated. Your body is worried about maximizing its ability to fight or run; it is not ready to eat a meal.

If, however, you are in a relaxed state, the thought of food, the sight of food, or simply making a mental association with food, sets into motion a series of events that prepares the GI tract for incoming food. Upon sensing that eating is imminent, the parasympathetic nervous system prepares the GI tract via signals sent through three cranial nerves that exit from the brainstem: the vagus nerve (cranial nerve X), the trigeminal nerve (cranial nerve V), and the glossopharyngeal nerve (cranial nerve IX).

**Preparation in the mouth.** In the mouth, food must be wetted by saliva, so you can taste it, chew it, begin to break it down into smaller particles, and swallow it. When your parasympathetic nervous system is stimulated, cranial nerves V and IX stimulate the salivary glands to release saliva into the mouth. The average person produces about 1500 ml of saliva each day.

Once food is wet, it can be tasted. Tasting food is critical for identifying it, receiving pleasure if it tastes good, rejecting it if it tastes bad, and for signaling to the

body that food is indeed about to be ingested. There are five primary tastants: sweet, sour, salt, bitter, and umami, which is the taste of the amino acid glutamate, a major ingredient of monosodium glutamate (MSG). Tasting is accomplished by taste receptors, which are located in structures called taste buds. Taste buds are housed in small bumps on the tongue and the roof of the palate called papillae. Fungiform papillae house the taste buds located on the anterior surface of the tongue, foliate papillae house taste buds that are located toward the back and side of the tongue. Circumvallate papillae, which form the chevron-like pattern in the back of the tongue, house very large numbers of taste buds. In addition, there are a scattering of taste buds in the palate, the posterior oropharynx, and the esophagus. It is interesting to note that the ideas that only sweet can be tasted at the tip of the tongue, only sour and salt can be tasted on the sides of the tongue, and only bitter can be tasted at the back of the tongue are myths. In fact, all taste buds are capable of tasting all tastants; however, they do so at varying levels of sensitivity.

Another reason for wetting food in the mouth is that it makes food easier to masticate and swallow. Furthermore, once food is chewed, it can be acted upon by salivary enzymes, which are compounds that work to chemically break down food into its molecular components. For example, saliva contains the enzyme salivary amylase, which begins the breakdown of carbohydrates, and lingual lipase, which begins the digestion of fat.

**Preparation in the stomach.** Food needs to be mixed with fluid in the stomach as well. Therefore, upon the initial cue that the arrival of food is imminent, cranial nerve X (the vagus nerve) stimulates the stomach to release the gastric juices that will be necessary for digestion. Contained in the gastric juices are water, hydrochloric acid (HCl), and pepsin, an enzyme that breaks down proteins in the stomach’s acid environment. Water is necessary to keep food liquified. Hydrochloric acid serves several purposes: it signals further digestive events to occur; it dissolves food into smaller particles; it kills many microorganisms that may have been ingested; and it denatures proteins, causing the proteins to lose their structure so that they can be further digested.

In response to parasympathetic activation, the stomach also produces a protective coat of mucus. There are two types of mucus, visible mucus and soluble mucus, consisting of highly glycosylated proteins, called mucins. Mucous neck cells that surround the openings of the stomach’s acid-producing glands (called gastric or oxyntic glands) produce visible mucus, which continuously forms a protective coat on the surface of the stomach. As the gastric gland sends out hydrochloric acid and enzymes, soluble mucus, formed by the cells that line the upper part of the gastric pits, is secreted ahead of it, and also covers the surface of the stomach. Together, the two types of mucus form a protective coat, called the glycocalyx. This coat is soluble in alcohol, while aspirin pre-

vents the formation and secretion of mucin. Therefore, alcohol abuse, or excessive use of aspirin, can permit hydrochloric acid to attack the stomach lining, which leads to bleeding. In addition, individuals who are highly anxious do not experience proper parasympathetic activation when eating, and consequently do not produce sufficient mucus. Therefore, given the presence of other triggers for ulcer formation (and specifically infection with bacteria of the *Helicobacter* species), anxious individuals are often susceptible to peptic ulcers.

**Preparation by the pancreas.** Cranial nerve X stimulates the pancreas to release insulin from its beta cells. Insulin is the hormone responsible for moving glucose and amino acids out of the blood and into cells so that they can be used for fuel and for forming new or renewed tissue. Insulin is needed once food is digested and absorbed, because the concentration of glucose and amino acids in the blood then increases. Cranial nerve X also stimulates the pancreas to release bicarbonate into the small intestine, which will be used to neutralize the acid coming from the stomach. This process will be discussed in more detail in a later section.

### **Ingestion: The Mouth and Esophagus**

Once the digestive system has properly prepared itself for its incoming meal, food is ingested. Food is wetted by saliva, tasted by the tongue and palate, and chewed or masticated by the teeth. Once the food is mechanically broken down into small enough pieces, it is ready for swallowing, or deglutition. Swallowing is actually a complicated process that requires coordinated activity of the tongue, palate, pharynx, and esophagus, over twenty-two muscle groups in all, controlled by separate regions of the brain. This activity requires strict control to guarantee that the food makes its way into the esophagus and not the trachea. If food is swallowed into the trachea, breathing is blocked and choking ensues. Once food enters the esophagus, the tongue blocks the mouth, the palate rises to close off the nasopharynx, and the larynx rises so that the epiglottis, a muscular flap, covers its opening into the respiratory passageways. Food is subsequently squeezed through the pharynx and into the esophagus by wavelike peristaltic contractions.

At the bottom of the esophagus is the cardiac or lower esophageal sphincter. The esophageal sphincter acts like a valve controlling the entry of food into the stomach. With each peristaltic contraction, the esophageal sphincter opens and a bolus of food lands in the stomach. The esophageal sphincter is also designed to stay closed while the stomach contracts, so that the acid from the stomach cannot reflux into the esophagus. The burning a person feels when acid refluxes into the esophagus is commonly known as heartburn.

### **Breakdown and Digestion: The Stomach**

The stomach is responsible for a large proportion of both the mechanical and chemical breakdown of food. Once

The act of eating, and some of the psychological pleasures connected with it, are captured in this photograph of a teenage girl nibbling her way through a cupcake. © LARRY WILLIAMS/CORBIS.

it accomplishes its goal, it delivers the resulting material (called chyme at this point) into the small intestine, at a rate that is dependent upon the mixture it digests.

The stomach is anatomically designed to stretch to accommodate the entry of food, and to churn and mix food thoroughly so it may be acted upon by stomach secretions and enzymes. At the top of the stomach is the fundus, a dome shaped section where the majority of hydrochloric acid is secreted. Below the fundus is the body of the stomach. The body of the stomach and the antrum of the stomach are separated by the incisura. Below the incisura is the antrum, which narrows and terminates at the pylorus. The pylorus opens into the duodenum through the pyloric sphincter, a muscular valve that controls the emptying of chyme into the duodenum.

**When food arrives in the stomach.** When food arrives in the stomach, the esophageal sphincter closes; the stomach muscles relax, with the result that the pressure inside the stomach decreases. These two actions prevent food

## CHINA AND EATING: TAOIST FIVE ELEMENTS

The Chinese healing tradition is centered on a fundamental concept—balance—and three fundamental ways of delineating the elements involved in this balance: yin and yang, or the principle of opposites that are complementary and mutually dependent; the Taoist concept of the five elements or five evolutions; and the concept of *qi*, or “intrinsic energy.” Daily eating should promote a harmonious balance among these systems, while eating in times of disease should be managed in order to restore balance.

Traditional Chinese knowledge of the anatomy of the digestive organs is reasonably accurate. However, the physiological concepts based on the ideas outlined above differ considerably from their Western counterparts. All parts of the body, and actions of the body, have either a yin or a yang quality. Eating is yin, while bodily activity is yang. Thus overeating causes an excess of yin, and can only be compensated for by increasing yang, for example, by exercise. Foods themselves have yin or yang qualities, so that a properly balanced meal is one where foods are chosen in order to balance their yin and yang qualities.

The organs of digestion are each either yin (liver) or yang (stomach, small and large intestine, gallbladder). Emotions affect the balance of function of these organs, so that, for example, anger affects both the liver, the organ corresponding to yin, and the gallbladder, corresponding to yang, leading to dysfunction of both.

The Taoist five elements (wood, fire, earth, metal, and water) can be used to classify the organs of the digestive system, as well as tastes and smells, the orifices

and tissues of the body, the emotions, and natural phenomena such as the seasons. The order of the elements also provides directionality, in the sense that the Elements follow each other in the order of their corresponding seasons, and the function of one organ is dependent on the good function of the organ preceding it in the sequence. Furthermore, this scheme functions in parallel with the yin/yang system, so that, for example, both the liver, a yin organ, and the gallbladder, a yang organ, correspond to wood, and anger, being associated with both of these organs, corresponds to wood as well.

As the “intrinsic energy” of the body, *qi* is critical to the processes and transformations that move food to its appropriate location in the body, and transform it into nourishment. Each food provides its quota of *qi* or activation of *qi*, or, if toxic, depletes or stagnates *qi*. In health, foods can help *qi* move downward through the “triple burner,” consisting of the three divisions of the torso: the upper burner, devoted to respiration and containing the lungs and the heart; the middle burner, devoted to digestion and containing the spleen, stomach, liver, and gallbladder; and the lower burner, devoted to elimination, and containing the kidneys, bladder, and lower intestines. For example, radishes are thought to help *qi* move downward and thereby promote digestion and good health.

Thus these three interlocking systems serve to organize and direct eating behavior by providing a scheme for balancing the perceived characteristics of each food eaten and each health condition experienced.

from refluxing back into the esophagus. The stomach's relaxation reflex is also designed to accommodate the increased volume and develops in response to the stretching of the stomach's walls. Note that this relaxation reflex can be “trained.” When a person regularly eats large meals, relaxation is greater, and when a person eats small meals, the relaxation reflex is less vigorous. This less vigorous reflex is why people feel their stomach “shrinks” when they go on a diet.

Hydrochloric acid is secreted by parietal cells in glands of the fundus of the stomach. As a result, the pH in the fundus can be on the order of 1–2. With this low pH, pepsinogen, secreted by chief cells, also located in these glands, is converted to pepsin. Pepsin breaks down protein-containing foods in the fundus into peptides and amino acids, and calcium and vitamin B<sub>12</sub> are released. These food components arrive in the antrum, where they

induce the production of the hormone gastrin. Gastrin travels via the blood to the fundus to increase hydrochloric acid secretion. Incidentally, due to this signaling function of protein in the stomach, it is nutritionally important to consume some protein with each meal. Gastrin also enhances closure of the pylorus and esophageal sphincter. Local histamine secretion sensitizes parietal cells to the effects of activation the vagus nerve and of gastrin. These three processes form a carefully coordinated system that is designed to maximize hydrochloric acid secretion and retention of material in the stomach so that it is properly mixed with each wave of contraction.

To prevent dumping of the stomach's contents into the duodenum, the pylorus closes, so that only about one-tenth of the amount of food that entered the stomach actually reaches the duodenum immediately after ingestion. As the pylorus closes, the area around the incisura con-

tracts; this provides a narrow round opening separating the antrum from the body and fundus of the stomach. The antrum then contracts, shooting the food back through this narrow opening into the fundus, a process known as retropulsion. As mentioned above, the fundus secretes hydrochloric acid, so the food, the hydrochloric acid, and the enzymes become thoroughly mixed. At the same time, fats are broken down into small globules through this churning process. The incisura then relaxes, and the food mixture is propelled forward into the antrum. This process repeats itself time and time again.

***Digestion in the stomach.*** As noted earlier, proteins are first digested in the stomach by an enzyme called pepsin. Pepsin breaks down protein into smaller molecules called peptides or polypeptides, which make their way into the small intestine for further digestion and absorption.

The digestion of fat begins in the stomach as well, through emulsification by churning and retropulsion. Fats that we consume are mostly in the form of triglycerides. A triglyceride is a molecule that has a glycerol backbone and 3 fatty acid chains attached to it. Fats are not water soluble (“oil and water do not mix”) and therefore need to be packaged for absorption into the blood. One process that aids in the digestion and packaging of fat is emulsification. Emulsification increases the surface area of the fat that is available for enzymatic action in the duodenum.

Finally, the stomach secretes intrinsic factor, which is required for vitamin B<sub>12</sub> absorption in the intestine. Vitamin B<sub>12</sub> is a large molecule, and requires intrinsic factor to protect it from destruction by the stomach, and to enable its absorption through a specific receptor in the ileum.

***Reflexes designed to clear out the lower GI tract.*** Before chyme can adequately make its way into the small intestine, there is a series of reflexes that are designed to prepare the lower gut (small and large intestine) for digestion. The result of these reflexes is that the lower gut gets cleared of old material so that there will be room for the new material coming down.

One reflex is known as the gastrocolic reflex and is due to stretching of the stomach after food lands in it. This reflex moves fecal material into the rectum, so you have a desire to defecate. This is why you may need to go to the bathroom after eating, especially after breakfast.

Gastrin is involved in the gastro-ileal reflex. This reflex clears chyme from the ileum, the furthest point of the small intestine, moving the chyme into the colon. Finally there is a duodenocolic reflex that is brought about when chyme enters the duodenum. This reflex also brings fecal material into the rectum in preparation for defecation.

### **Digestion and Absorption: The Small Intestine**

After the chyme is thoroughly mixed in the stomach, it moves into the small intestine. The small intestine is the primary site for the chemical digestion and the absorp-

tion of food. The small intestine has three subdivisions: the duodenum, the jejunum, and the ileum. The duodenum, which connects to the stomach, is the point of entry for the secretions from the pancreas and from the liver via the gall bladder. The jejunum is the longest section of the small intestine and is the site where the majority of nutrients are absorbed. The ileum is the third division and connects to the beginning of the large intestine.

The small intestine is anatomically designed for efficient nutrient absorption. Not only is it very long, but it also has three structural modifications which further amplify its absorptive area: plicae circulares, villi, and microvilli.

The plicae circulares are deep folds of the intestinal mucosa which force the chyme to spiral through the lumen of the intestine. This effect slows the movement and increases the mixing of the chyme, thereby creating time for maximal nutrient absorption.

Villi are fingerlike projections that lie on the surface of the plicae. These projections increase the amount of contact between the surface of the intestine and the chyme, and they make absorption more efficient because they each contain a dense capillary bed and a lymphatic capillary called a lacteal, which act to transport nutrients into circulation. Lacteals are essential for fat absorption.

Finally, at the end of each villus cell are tiny microscopic projections called microvilli, which form the intestine’s brush border. The microvilli dramatically increase the absorptive surface area of the small intestine. Moreover, there are enzymes that reside on the brush border that complete the final stages of chemical digestion of carbohydrates and proteins.

***When chyme arrives in the duodenum.*** Chyme must enter into the duodenum at a rate the duodenum can handle. Furthermore, the acidic mixture must be neutralized so that it does not damage the duodenum. Finally, the digestion of the chyme must continue, and the process of nutrient absorption must begin.

It is important to note that the hormones and nerve activities discussed below are usually responsible for more than one of these above processes, and that more than one hormone or nerve activity is involved with each of these processes. In other words, the digestive system has in place a number of checks and balances to ensure that each responsibility is met during intestinal digestion and absorption.

Gastric inhibitory peptide (GIP), released by the small intestine, is one such hormone. As its name suggests, GIP inhibits gastric motility, thereby slowing down the delivery of chyme to the duodenum. In addition, GIP is responsible for helping tissues prepare for an influx of glucose, by causing release of insulin from the beta cells of the endocrine pancreas.

Other ways in which the flow of chyme is slowed enough to accommodate digestion and absorption are

through intrinsic nerve signals from the gut, through a decrease in the activity of the vagus nerve or an increase in sympathetic activity, through the hormones secretin and cholecystokinin-pancreozymin (CCK-PZ), which are secreted by the duodenum in the presence of chyme. Not surprisingly, these hormones also have several other functions, discussed below.

In order for the digestive enzymes of the small intestine to be activated, they have to be in an alkaline environment. Neutralization of stomach acid is accomplished by secretions from the pancreas and from Brunner's glands, which line the duodenum. Both secretions are rich in bicarbonate, a basic compound that neutralizes stomach acid. The process of secretion for both of these systems begins with activation of the vagus nerve, which itself begins with the thought of food, as noted earlier. Secretion is further enhanced by secretin and CCK-PZ release from the duodenal wall in response to fat and amino acids in chyme. Vitamins and minerals do not require digestion for absorption.

***Fat digestion and absorption.*** In the small intestine, fat is further emulsified by bile, a fluid that is produced in the liver and stored in the gallbladder. The release of bile into the duodenum is induced by contraction of the gallbladder, which propels the bile into the common bile duct, and from there into the pancreatic duct. The sphincter of Oddi relaxes, letting the bile and pancreatic juices flow into the duodenum. Contraction of the gallbladder, relaxation of the sphincter of Oddi, and release of pancreatic juices are all induced by cholecystokinin-pancreozymin (CCK-PZ), produced, as noted above, by the duodenal wall in response to the presence of fat and amino acids.

Once fat is emulsified by bile, it can be acted upon by enzymes called lipases, which break down fat. Pancreatic lipase requires a high pH for activation, which is accomplished through secretion of pancreatic bicarbonate. Pancreatic lipase breaks off fatty acids from the triglyceride's glycerol backbone, leaving a monoglyceride and two fatty acids. Bile acids then join up with the monoglycerides and fatty acids to form mixed micelles. Bile salts need to be present at or above the proper concentration—the critical micellar concentration, or CMC—in order for micelles to form.

Mixed micelles are shaped like hockey pucks, with bile salts forming the outer ring of the micelles, and the hydrophilic (water-soluble) ends of the fatty acids and monoglycerides forming the circular surfaces. Because of this packaging, the micelles can cross the water layer at the surface of the cells of the small intestine. It should be noted that long-chain triglycerides (>12 carbons) require both breakdown by lipase and incorporation into mixed micelles in order to be absorbed, while medium-chain triglycerides (with 8–12 carbons in each fatty acid chain) only require breakdown by lipase, and not micelle formation, because they are more hydrophilic.

Bile acids are recovered from the chyme in the terminal ileum, and returned to the liver for re-use. Note that the terminal ileum is also where vitamin B<sup>12</sup> is absorbed. No other part of the intestine can compensate for these functions should the terminal ileum be diseased or lost, although absorption of other nutrients can occur successfully with loss of a considerable length of jejunum.

***Carbohydrate digestion and absorption.*** Carbohydrates are also digested and absorbed in the small intestine. They are hydrophilic compounds, and therefore do not require complex packaging to be absorbed. Carbohydrates in our diet exist as monosaccharides, which are one sugar unit long (simple sugars: e.g., glucose, fructose, and galactose); disaccharides, which are two sugar units long (e.g., sucrose, lactose, and maltose); and polysaccharides, which are long complex strings of sugar units (e.g., glycogen and starch).

The majority of carbohydrates are consumed as polysaccharides, either as starch or glycogen. It should be noted that fibers, either soluble or insoluble, are types of polysaccharides that cannot be digested because we lack enzymes capable of chemically breaking them down.

Carbohydrates that can be digested begin to be broken down into small sugars in the mouth by the enzyme salivary amylase (noted earlier). You may have noticed that a piece of bread that you keep in your mouth for some time begins to taste sweet because the amylase in your saliva breaks down complex sugars into sweeter-tasting simple sugars.

The majority of carbohydrate digestion takes place in the small intestine via enzymes that are secreted by the pancreas. Pancreatic enzymes break polysaccharides down into oligosaccharides (2–8 sugars long), which are then acted upon by enzymes of the intestinal brush border. Within the brush border, oligosaccharides are further broken down into glucose, fructose, or galactose, depending on their initial composition. Glucose is the primary source of fuel used by cells in the body, and fructose and galactose can be converted into glucose via biochemical mechanisms.

***Protein digestion and absorption.*** Protein digestion in the small intestine is accomplished by pancreatic enzymes as well. The large polypeptides created by the action of pepsin in the stomach are broken down into small peptides and amino acids by the pancreatic enzymes trypsin, chymotrypsin, and carboxypeptidase, as well as by peptidases in the brush border. Amino acids, the smallest functional unit of proteins, and small peptides are then absorbed into the blood, where they can be transported to cells for protein synthesis or for fuel.

### **The Large Intestine: The End of the Journey**

The undigested portion of food that does not get absorbed by the small intestine passes on into the large intestine. The large intestine is responsible for reabsorbing the water added by the stomach and the small intestine

to keep the chyme fluid, for fermentation of undigested products by bacteria, and for packing waste products into feces for excretion. The subdivisions of the large intestine are the cecum, appendix, colon (ascending colon, transverse colon, and descending colon), rectum, and anal canal.

Bacteria normally live in the large intestine. These bacteria either make their way into the large intestine by surviving the journey through the stomach and small intestine, or via the anus. These bacteria break down the fiber that is consumed, releasing gases, as well as the very smelly short-chain fatty acids that provide the major source of fuel for the wall of the large intestine. In addition, these bacteria are capable of synthesizing some B vitamins and vitamin K.

Once the contents of the colon are moved along via contractions, they reach the rectum, which otherwise is usually empty. Stretching of the rectal wall initiates a defecation reflex. This reflex is mediated by the parasympathetic nervous system and causes the walls of the sigmoid colon and the rectum to contract and the anal sphincter to relax. Once feces are forced into the anal canal, the stretch sends a signal to the brain informing us of the need to defecate. Under normal circumstances, the defecation response is under voluntary control.

Such a complex process as eating, in which each step is predicated on the preceding one, is prone to large variations in normal function. Specifically, the timing and efficiency of each of the steps described here show wide variability both from person to person, and for different food choices and consumption patterns. Some people have rapid intestinal transit time, and some slow nutrients are more easily digested and absorbed from some diets than from others. However, the basic scheme outlined here holds true for all healthy people.

**ECOLOGY AND FOOD.** Naturalists and geographers have commented on human, food, and natural-

resource relationships throughout history. Religion and politics have influenced their ideas. Once, many societies strongly valued community and balance between nature and humans. With industrial modernization, the philosophy changed to conquering or controlling nature via education, "objective" science, new technology, and new ideology emphasizing individualism. Education in the fields of agriculture, soil science, genetics, and food science greatly expanded to explore and promote new methods for increased food production, processing, storage, and distribution. While tractors, machinery, chemical fertilizers, and pesticides sharply increased food production for a growing population (hailed in the 1960s as the "Green Revolution"), some pointed to the limits of natural-resource use and "progress."

#### Ecology, Science, and Modernization in Food Production and Distribution

Ecology—or *Ökologie*, as coined by German biologist Ernst Heinrich Haeckel in 1911—was largely a twentieth-century development. In this perspective studied in the natural sciences, the world is an interrelated system where changes in one part of the system affect everything else. The sun's energy and the earth's minerals nourish a cycle of plant "producers," herbivore "consumers," carnivore and omnivore "consumers," and bacteria, fungi, and parasite "degraders" that return the organic waste of the producers and consumers back into the system. The plant producers, animal consumers, and microorganisms are all food to each other, with humans generally being among the omnivores. Overall population of plants and animals is limited by the resources available to consume, as well as the ability to adapt to environmental stressors such as extreme weather, disease, or toxic waste. Ecological systems are more stable, or in balance, when a large number or diversity of plant and animal species is present, rather than few species in any location. Hence, forests or prairies are more diverse and stable than hog farms or cornfields, whose single species are highly susceptible to environmental stressors. Intercropping and crop rotation allow some diversity, even though the plant varieties are nevertheless limited.

Human systems studied through anthropology or geography gave rise to cultural ecology, human ecology, and political ecology, as understanding of ecological complexity grew. Cultural ecologists studied human cultures around the world as a product of desert, grassland, temperate forest, rain forest, mountain, or tundra environments in which people live. Each human culture was characterized by its particular foods and processes for daily living that were particular to the environmental qualities and limitations of these different habitats. Viewed within the industrial modernization paradigm emphasizing specialized technology, cultural evolution was measured by how much energy was harnessed from the environment per unit of human caloric input for hunter-gatherers, early small-scale cultivation and animal

## FOOD PRODUCTION COSTS AND BENEFITS

The tremendous nonhuman energy fuel inputs in the more technological modern societies demonstrate ecological imbalance. The United States, for example, has one-twentieth of the world's population, but uses one-third of the world's fuel resources. Growing one calorie of food requires three calories of fossil fuel input for machinery, electricity, and fertilizer, and at least nine calories of fuel when processing and market transportation are included. This still excludes building the transportation vehicles, roads, and factories.

Genetic breeding of high-yield seeds and animals has led to more monocropping and less genetic diversity in the globalized cash-crop agriculture. Often the seeds are hybrids that do not reproduce new seeds to grow crops, so farmers must purchase each year's seeds from the agricultural industry. Nor are the high-yield seeds adapted to environmental stressors in diverse habitats without purchased chemical fertilizer and pesticide inputs. While new chemical pesticides are less immediately toxic than old arsenicals, cyanide, or nicotine, DDT (dichloro-diphenyl-trichloroethane) fatally weakens birds' eggs nearby, and there have been strong sugges-

tions of a link between pesticides (particularly DDT) and the tumors, reproductive problems, and cancer that occur among farmhands who have direct and repeated contact with the chemicals. Thus pesticides' long-term safety to consumers and the environment is questioned by those such as biologist Rachel Carson, who in 1962 exposed the dangers of pesticides in her seminal book, *Silent Spring*.

Also, farmers receive much less income for their food-production efforts compared to others in the overall marketing system. The twentieth-century Green Revolution that was to produce volumes of food for global markets also produced environmental and cultural degradation as traditional food-production practices, decision-making, and locally adapted seed and animal varieties were replaced. Since Neolithic times, increased crop volume has not necessarily produced better nutrition, since food distribution, access, and nutrient quality of the ensuing diet are frequently inadequate. High food volume allows high population density, increasing the risk of infectious disease because of waste management problems and peoples' proximity to each other.

husbandry, more advanced agriculture of state societies, and then global industrial society. Animal, mechanical, transportation, and fossil-fuel inputs were often overlooked so that technological modernization was perceived to produce great volumes of food and caloric energy for the exponentially growing population.

Human ecologists further examined ecological interrelations of humans, food production, and consequent health status in different habitats. Calculating detailed energy flow of food and fuel calories in particular groups' ecological systems illuminated the limits of the natural environment, and the adaptiveness of people's physiology and behavior to particular environments, foods, and climate. Human ecologists, like Michael Watts, defined the causes of severe droughts and food shortage in sub-Saharan Africa in the mid-1970s and 1980s. Since drought is cyclical, human ecologists investigated how traditional populations avoided famine via many traditional strategies to modify, buffer, distribute, resist, avoid, or conform to the perturbation. Food storage techniques, crop diversity, and irrigation are prime examples of buffering, distributing, or modifying environmental stressors. Continued use of such indigenous knowledge was recommended. Researchers also began to understand how the limits of natural-resource accessibility have been controlled by local, regional, and global politics and eco-

nomic market forces throughout history. Political and economic decisions made by new groups resulted in short-term gains, which often disrupted the longer-term environmental sense of traditional practices that had permitted people to survive over time. Hence, political ecology became the study of these combined factors, to improve food production further.

### Environmentalism and Scientific Ecology

Some argue that the conservation movement arose through scientific application of ecological concepts so as to rationally plan economic development, thus replacing the public's or business's inefficient, shortsighted use of natural resources. Others believe that conservation occurred in reaction to modern industrialization's political grip over nature and people. Nevertheless, the environment has been known through an emotional, spiritual relationship of people who identify with their natural surroundings. Academic ecology initially had the premise that, by understanding ecological relationships, one could better control the parts of the process. "Objective" science and technology was the tool of industrial modernization's goal: controlling nature and other humans. Many public environmental movements identified with earlier religious and political philosophies oriented to the beauty and balance in nature, whereby taking too much

from the system sends it into imbalance and ecological disaster.

Environmentalism has various forms that consequently advocate different philosophies and strategies for maintaining a balance among humans and the natural environment. Radical environmentalism includes deep ecology, social ecology, and ecofeminism. Radical environmentalism suggests eliminating the current political economic system to reach a more environmentally sound existence, whereas “surface” ecology advocates tinkering within the current system to direct it toward more sustainable or lower-impact options. Contrasts in environmental approaches have long existed, as reflected in John Muir’s transcendental philosophy and Sierra Club in the early 1900s, versus Chief U.S. Forester Gifford Pinchot’s scientific resource management of agriculture, forestry, livestock, and mining lands during Theodore Roosevelt’s administration (1901–1909). Other environmentalists would emulate Aldo Leopold, who in the 1930s departed from scientific resource management to more spiritual approaches. Many scientific ecologists also gain insight from philosophical teachings and select career objectives that will serve the needs of humans and nature.

### **Sustainable Agriculture and Globalization**

The counterculture of the 1960s and 1970s heightened interest in “health food” and food co-ops. This, and returning to organic farming, bioregional marketing, and sustainably “living off the grid” were reactions to capitalist globalization, vertical integration, and concentration in the food industry. Vertical integration involves ownership of the entire process of food production, processing, shipping, and marketing by a corporation or set of related corporations. The corporation may subcontract the riskier lower-profit aspects of the process to a separate small business that coordinates the farmers to meet the corporation’s demand for specific qualities and timing of crop or livestock production. Concentration involves controlling entire food types (for example, pork, chicken, or flour) by only a few corporations. Contrastingly, community-supported agriculture and local farmers’ markets feature direct marketing between the farmer and consumer.

The U.S. Food and Drug Administration (FDA) began as the “Division of Chemistry,” created in 1862 as an agency of the Department of Agriculture and charged with the responsibility of regulating toxic food additives, preservatives, quack drugs, and insecticides. However, the FDA (so named in 1930) has become associated with industrial pharmaceutical business, authoritative curative medicine, and health-insurance interests by those preferring self-directed disease prevention with “health” foods and herbal and vitamin supplements. Vegetarian and organic products are often selected for reasons philosophical (to protect animals) or environmental (to eat chemical-free or low on the food chain). Europeans react strongly against genetically modified food because of

### **RADICAL ENVIRONMENTALISM: DEEP ECOLOGY, SOCIAL ECOLOGY, ECOFEMINISM**

The term “deep ecology” was coined in the late 1960s by its leading proponent, Arne Naess, Norwegian mountaineer and teacher of Eastern and Western philosophy. Bill Devall and George Sessions, as well as David Foreman (founder of the radical group Earth First!) are more recent promoters. According to deep ecologists, the natural world is understandable through deductive subjectivity and consciousness raising. Examples of nature’s value are gleaned from many religious philosophies. Population control and the biocentric valuing of plants and animals are deep ecology’s hallmarks, rather than an anthropocentric orientation based on human needs. This has disturbing political implications when applied by elite classes or countries to the global system, since wildlife preservation is promoted over human needs in poverty-stricken areas. Neglect of these human needs becomes, therefore, population control.

Murray Bookchin pioneered the idea of “social ecology” in the 1960s as a means to address social inequity and sustainability by arguing for a more equitable decentralized political economic system using more alternative technology. But social ecology’s Marxist and German Greens influences are often contrary to the philosophy and practices of the modern global market system. According to Bookchin, the natural and human ecological system develops through an educative, mediated, cumulative approach, versus the deductive understanding of nature, or the mechanistic evolutionary continuum of modernization found in deep ecology.

“Ecofeminism,” promoted especially by female social scientists, notably Carolyn Merchant, explains environmental degradation and means for balance based on historical inequity of male and female social relations and decision-making. However, numerous evolutionary, structural, and political economic paradigms are confounded in selection of examples, much as deep ecology muddles religious philosophy from stratified and egalitarian social systems. According to ecofeminists, ritual, myth, and intuition are among methods of women’s knowing, versus authoritative knowledge of male-centered “objective” science, business, and politics.

possible harm to others in the food chain, and against large-scale animal-husbandry practices that increase infectious disease, such as animal foot-and-mouth disease

or “mad cow” disease—also feared for suspected neurological problems in humans. Yet the health-food market is subsumed by the corporate vitamin and supplement industry; the industrialization and mass marketing of “organic,” “natural,” or “health” food (a world market worth more than twenty-two billion dollars annually); more chain stores; and the U.S. Department of Agriculture’s national organic standards of December 2000. Previous standards varied among regional organic farming associations, some being so strict that industrial organic farming would be prohibitive.

Interestingly, industrial and alternative agriculture claim overlapping goals, although careful examination reveals very different ideals behind those goals. Industrial corporations see a sustainable food system as ecologically sound, economically viable, and socially acceptable. When asked to identify their visions of a food system, supporters of alternative agriculture use such terms as ecologically sustainable, knowledgeable and communicative, proximate, economically sustaining, participatory, just and ethical, sustainably regulated, sacred, healthful, diverse, culturally nourishing, seasonal and temporal, economically value-oriented, relational. Conventional, industrial agriculture—centralized, dependent, competitive, specialized, and exploitative—attempts to dominate nature and the enterprise. Alternative agriculture is decentralized, independent, community-oriented, and restrained, with an emphasis on diversity and harmony with nature. The former maintains company profits; the latter attempts to maintain broader sociocultural and biological integrity of the local community and ecosystem.

**EDUCATION ABOUT FOOD.** Traditionally, chefs’ proprietary interest in their culinary knowledge has hindered their efforts to educate successors. Before the late eighteenth century, culinary education meant apprenticeship in private—or royal—kitchens. To some extent, it still does mean that, although modern kitchens are more commonly commercial. Today, culinary education other than apprenticeship occurs in two primary forms: formal and independent, each subdivided into professional and domestic training.

#### Formal Study

In the late eighteenth century, chefs began to seek the respect accorded to other professionals. Recognizing that formal education is required for professional status, E. Kidder opened the first school for chefs in England in 1781. It was not until 1874, however, that the prestigious London Cookery School emerged. The pioneer French culinary school, École Professionnelle de Cuisine et des Sciences Alimentaires, debuted seventeen years later, but was short-lived (1891–1892). Le Cordon Bleu (1895), the first truly successful professional cooking school, became the prototype for most subsequent culinary programs.

Outside the United States, culinary schools generally issue certificates, not degrees. Since the end of World War II, many American chefs have been educated in collegiate culinary programs, receiving degrees from Cornell’s School of Hotel Administration (1922), The Culinary Institute of America (1946), Johnson & Wales University (1973), or dozens of other colleges.

Cooking schools for domestic (primarily female) cooks began earlier than those for professionals. The first American cooking school, Mrs. Goodfellow’s, opened in Philadelphia around 1820. Its anonymous textbook *Cookery As It Should Be* (1853) was reprinted in 1865 as *Mrs. Goodfellow’s Cookery As It Should Be*.

The learning experience of a cooking school for young ladies is the subject of this John Leech caricature in 1851. The student in the center is curtsying although holding her ground: "I think I know my plum pudding!" On the right, another student bemoans that she will never learn how to make a proper omelet. From John Leech's *Follies of the Year* (London, 1864). ROUGHWOOD COLLECTION.

The Boston Cooking School (1878) was the most influential of the early cooking schools, resulting in the publication of *Mrs. Lincoln's Boston Cook Book: What To Do and What Not To Do in Cooking* in 1884. Fanny Farmer's *The Original Boston Cooking-School Kitchen Cook Book* (1896) applied scientific structure and principles in the home kitchen—foreshadowing Auguste Escoffier's *Le Guide Culinaire* (1903), which attempted to do the same for the professional kitchen.

### Independent Study

Early professional cookbooks—written by and for men—such as Apicius's *De Re Coquinaria* (first century) or the *Viandier of Taillevent* (fourteenth century) were simply collections of recipes. They did not attempt to teach technique because they were intended for professional cooks who—presumably—understood their vague, missing, or abbreviated instructions. Charles Carter's cookbook, *The Complete Practical Cook: Or, A New System of the Whole Art and Mystery of Cookery* (1730), was typical of early cookbooks in that it was written for the management of wealthy households, but it consciously strove to educate the reader in the "most useful and noble Mysteries of their Art."

Most early home cookbooks, such as Torquatto Tasso's *The Householders Philosophie* (1588), were intended for women. They featured cooking instruction as just one of the duties comprising home economics or "domestic

science." Home economics was envisioned—especially in the late nineteenth and early twentieth centuries—as a way to modernize—and professionalize—women's household work with "scientific" respectability. The Boston Cooking-School's textbook (1887) was such a treatise on "domestic science."

The earliest professional magazines for chefs and bakers—*L'Art Culinaire* (not the *L'Art Culinaire* available today), *Le Progrès des Cuisiniers*, *L'Étoile* and *Le Progrès Gastronomique*—first appeared in the 1880s. Today, there are hundreds of trade magazines for food professionals in almost every imaginable language. Even more food magazines are targeted at home cooks, and almost every major newspaper carries at least a column—and, more often, an entire section—devoted to food preparation.

Televised cooking lessons have grown in popularity and sophistication since Julia Child's *The French Chef* (1963). An entire network is now devoted to food programming—although it is intended largely for amateur cooks. The Culinary Institute of America and the California Culinary Academy (1977), however, produce series for public television that teach professional techniques for home use.

The Internet is a major supplier of culinary information for both home and professional cooks, offering recipes, reviews (of books and restaurants), nutritional data, links with TV cooking shows, and dozens of specialized culinary discussion groups.

## Food Studies

Aside from cooking instruction, "Food Studies" is beginning to be recognized as a legitimate scholarly subject in its own right. Today, one can earn a master's degree in gastronomy at Boston University or the University of Adelaide, or a doctorate in Food Studies and Management from New York University.

Professionals in food science and nutrition have long had academic societies, but more recently scholars working in food studies have formed such groups. The Oxford Symposia on Food and Cookery (1981) provide opportunities for scholars from diverse backgrounds to share their research. The Association for the Study of Food and Society (1986) and the Agriculture, Food and Human Values Society (1987) promote research and scholarship on food-related issues, drawing on disciplines as diverse as anthropology, sociology, geography, literature, nutrition, and history.

Excellent culinary libraries—including the Arthur and Elizabeth Schlesinger Library on the History of Women in America (Radcliffe College); the James Beard Foundation Archive and Library (New York); the Conrad N. Hilton Library (Culinary Institute of America); Culinary Archives & Museum (Johnson & Wales University); Foundation of Chinese Dietary Culture (Taipei); Foundation B. IN. G. (Bibliothèque Internationale de Gastronomie, Italy); and Bibliothèque Municipale de Beziers, Bibliothèque Municipale de Dijon, and G. Sender (France)—inform food scholars.

The American Institute of Food & Wine (1981) and the James Beard Foundation (1985) spread awareness of gastronomic excellence through education, publications, scholarships, and events. Oldways Preservation & Exchange Trust (1988) and Italy's Arcigola Slowfood (1986) are preserving the knowledge and practice of traditional foodways.

Several societies of professional culinary educators have been organized to enhance respect for chefs. The American Culinary Federation (1929) awards the culinary equivalent of a doctoral degree—Certified Master Chef (CMC)—and accredits over one hundred American culinary education programs. Similar groups include the Council on Hotel, Restaurant, and Institutional Education (1946) and the International Association of Culinary Professionals (1990).

Les Dames d'Escoffier (1976) and Women Chefs and Restaurateurs (1993) were formed specifically to advance the professional status of women in the food service industry, successfully doing for professional female culinarians what the domestic science movement attempted to do for home cooks.

**EGGS.** Eggs have been known to, and enjoyed by, humans for many centuries. Jungle fowl were domesticated in India by 3200 B.C.E. Records from China and Egypt show that fowl were domesticated and laying eggs for human consumption around 1400 B.C.E., and there is archaeological evidence for egg consumption dating back to the Neolithic age. The Romans found egg-laying hens in England, Gaul, and among the Germans. The first domesticated fowl reached North America with the second voyage of Columbus in 1493.

Eggs are a staple of the diet in most of the world. They are used as main dishes or served as garnish with other parts of the meal. Barer-Stein points out that Austrian and Croatian cuisines are rich in eggs. In Africa eggs are regarded as a symbol of fertility and accompany yams in many festive dishes.

While most discussions of eggs and egg nutrition refer to bird's eggs, it should be borne in mind that many other animal species also lay eggs. Among mammals the echidna and the duck-billed platypus lay eggs. Reptiles, among them lizards, chameleons, and the tuatara of New Zealand, lay eggs, as do toads and frogs. Mollusks and

TABLE 1

Proximate composition of a large raw egg		
(59 g shell, 33.4 g white, 16.6 g yolk)		
Nutrient	Whole egg (g)	% in yolk
Water	37.665	21.5
Protein	6.245	44.5
Carbohydrate	0.61	48.4
Fat	5.01	100.0
Ash	0.47	57.9

crustaceans lay eggs that appear in a variety of forms. The eggs of fish offer a wide range of number and form; for instance, salmon eggs are deposited in a trough prepared by the parent, while eggs of perch are adhesive and stick to water plants.

The number of eggs laid by fish varies widely but increases with age and weight. The salmon may produce 1,000 eggs for every pound of weight. The sturgeon lays about 7,000,000 eggs, whereas the herring and sole produce 50,000 and 134,000 eggs, respectively. The number of eggs laid is proportional to the risk of destruction or loss.

The greatest knowledge of eggs, their physiology and chemistry, comes from observing hens. The hen's reproductive system consists of the ovary, where the yolk develops, and the oviduct where the egg is completed. At birth the female chick has a fully formed ovary containing several thousand tiny ova, or future yolks. The ova begin to develop, one at a time, when the chick reaches sexual maturity. Each yolk is enclosed in its own sac or follicle. The follicle contains a system of blood vessels that supply nourishment to the developing yolk. At ovulation the follicle ruptures, thus releasing the yolk into the oviduct. The yolk passes into the infundibulum (funnel), where fertilization could occur. After about fifteen minutes the yolk passes into the magnum, where, in a period of three hours, albumen is deposited around the yolk. The yolk next passes into the isthmus where two shell membranes are formed in about seventy-five minutes. The egg has now achieved its full size and shape. It now passes into the uterus, where, over a period of nineteen to twenty hours, it acquires its shell, shell color, and outer shell coating. After a few minutes the egg is released via the vagina, cloaca, and vent. During formation the egg moves through the oviduct small end first, but just before laying, it is rotated and laid large end first. It takes the hen twenty-four to twenty-six hours to produce an egg. Within fifteen to thirty minutes after laying, the hen starts the process all over again.

The egg is designed to support life (to bring a chicken into the world) and has been called nature's ideal food. The yolk comprises about one-third of the weight

of the egg. The albumen or white of the egg is primarily protein and water. The yolk of a large egg contains fifty-nine calories and the albumen carries about seventeen calories. See Table 1 for the proximate composition of a large raw egg.

Protein is required for synthesis and maintenance of muscles, body organs, nerves, bones, and blood. Protein quality is measured by how efficiently it is used for growth. Only mother's milk has higher quality protein.

Egg protein contains different amino acids, including all the essential amino acids (essentiality of a nutrient means that it cannot be synthesized by humans and must be obtained from the diet).

Fat (lipid) comprises about 10 percent of the total weight of a large egg. The lipid composition of the egg is presented in Table 2.

Saturated, monounsaturated, and polyunsaturated fatty acids comprise 37.5, 46.0, and 16.5 percent of the total, respectively. Oleic acid (18:1) represents 40 percent of egg yolk fatty acids. There is a nutritional ambivalence with regard to eggs. Although the superior quality of egg protein is acknowledged, there is concern regarding the cholesterol content, this despite evidence that moderate intake of egg yolk is generally not harmful. Since polyunsaturated fats reduce plasma cholesterol levels, efforts have been made to increase their presence in the yolk. Feeding laying hens high levels of polyunsaturated fats such as corn or soybean oil will raise the level of their component yolk fatty acids to a slight degree. "Polyunsaturated" eggs are commercially available, but there is little evidence regarding any sustained hypocholesterolemic effect. There are also efforts to increase levels of antioxidant vitamins and fish oil

TABLE 2

Yolk lipids of a large raw egg	
(59 g shell, 33.4 g white, 16.6 g yolk)	
Fatty acids	G
Total	4.43
Saturated	1.59
Myristic (14:0)	0.02
Palmitic (16:0)	1.14

Floating island was one of the most popular meringue desserts in eighteenth-century English and American cookery. It is still popular in England today. Egg whites whipped with wine are shown here floating in a creamy Madeira sauce. The "island" is garnished with crystallized violet petals and toasted almonds.

© MICHAEL BOYS/CORBIS.

fatty acids in egg yolk and those products, too, are available to the public.

Hen's eggs are the most common source of egg nutrition. In 1989 the three largest egg-producing countries were China ( $140,900 \times 10^6$  eggs), Russia ( $84,600 \times 10^6$  eggs), and the United States ( $67,042 \times 10^6$  eggs). However, eggs of other avian species are eaten around the world. Hen's eggs contain less fat and less cholesterol than those of the duck, goose, quail, or turkey. The amount of fat in a yolk is partly a function of the size of the embryo and its future requirements. Caviar, for instance, contains almost 18 g of fat per 100 g of edible portion, but its cholesterol content is only 38 percent greater than that of the hen's egg. The major fatty acids of all the yolks are palmitic and oleic.

The egg is an easily available, inexpensive source of high-quality nutrition. It is an especially important source of nutrition for young people, old people, and sick people. Starting about forty years ago, as the relation be-

tween blood cholesterol and the risk of coronary heart disease was unfolding, the egg came under fire because of its cholesterol content. The assumption was that eating cholesterol-rich foods led directly to elevations in blood cholesterol and hence in risk of disease. That elevated blood cholesterol presents a risk for heart disease is fairly well established, but a direct link between dietary cholesterol and levels of blood cholesterol is not. Many other aspects of the diet influence blood cholesterol to a greater extent than does dietary cholesterol; principal among them are the amount of saturated fat in the diet and the type and amount of fiber in the diet. There are dietary prescriptions limiting the permissible amount of cholesterol in the diet. These are easy to follow, but are based on relatively little hard data. The emphasis on cholesterol has overshadowed the greater impact of saturated fat. The fat of the egg is relatively unsaturated, or the raw yolk would be solid. A calculated iodine value (measure of unsaturation) of egg yolk is about 72, which is not much below that of olive oil.

The relation of dietary cholesterol to blood cholesterol levels has been studied for many years. In the early 1950s it was demonstrated that while cholesterol levels of subjects with coronary disease were significantly higher than those of control subjects there was no relation to the level of cholesterol in the diet. In 1970 the subjects in the Framingham Study, both men and women, were segregated by serum cholesterol level under 180 mg/dl, over 300 mg/dl, and 181–300 mg/dl. The study found no correlation of serum cholesterol with any dietary component. The Framingham Study also showed that ingestion of one or nine eggs per week had the same influence on serum cholesterol. A study conducted by the NIH over twenty years ago attempted to correlate dietary factors with actual heart attacks in three large studies—Framingham, Puerto Rico, and Hawaii. At no location were there differences in cholesterol intake between those subjects who had suffered a heart attack and those who had not.

Epidemiological studies of dietary cholesterol have to be aware of possible confounding by other dietary factors. Many foods high in cholesterol are also high in saturated fat. High-fat diets are often poor in fiber. Since saturated fat intake has been linked to coronary disease and fiber appears to be protective, both must be considered when evaluating the role of dietary cholesterol.

Data relating dietary cholesterol to heart disease are available. A study of middle-aged men in the Netherlands showed no significant relationship between cholesterol intake and coronary death after ten years. A positive relationship appeared after twenty years of follow-up but was not significant after adjustment was made for standard risk factors, occupation, and energy intake.

More pertinent to the discussion is the relationship, if any, between egg consumption and coronary disease. A study of women in Italy found no association between

egg consumption and nonfatal myocardial infarction. A study among Seventh Day Adventists in California found no association between egg consumption and risk of cardiovascular disease, whereas a study of vegetarians in Oxford, England, found a significantly greater risk in those consuming six or more eggs a week than in those eating less than one egg per week.

One study, conducted at Harvard University, was aimed at investigating an explicit relationship between egg consumption and risk of cardiovascular disease. The authors addressed data derived from ongoing studies of more than eighty thousand female nurses and more than forty-three thousand male health professionals. After adjustment for age, body mass index, cigarette smoking, parental history of heart disease, vitamin intake, alcohol use, hypertension, physical activity, energy intake, bacon consumption, and in the women, menopausal status and postmenopausal hormone use, there was no association between egg consumption and coronary heart disease in either group.

The diet-heart hypothesis holds that a diet high in saturated fat and cholesterol and low in polyunsaturated fat leads to hypercholesterolemia and subsequent development of atherosclerosis. Addition of eggs to the usual diet of free living subjects does not affect cholesterol levels. Addition or deletion of eggs in the diet leads to other changes in diet that must be evaluated and corrected for. The Framingham data suggest that addition of eggs to the diet does not affect serum cholesterol levels. The egg is a source of a number of essential nutrients; that, plus its high-grade protein and low price, make the egg a desirable food, especially for the very young, old, and infirm. The presence of a high level of cholesterol in the egg has led to suggestions that it not be included in healthful diets since elevated blood cholesterol is a risk factor for cardiovascular disease. Data are accumulating which show that dietary cholesterol has a minimal effect on blood cholesterol levels. Epidemiological data also show little association between eggs and risk of cardiovascular disease. Eggs can be an important part of the diets of healthy persons.

**ELECTROLYTES.** Electrolytes are molecules that, in solution, dissociate into positively charged ions (cations) and negatively charged ions (anions). Principal ions in body fluids are sodium, potassium, and chloride. A 70 kg adult has a body content of approximately 100 g sodium, 140 g potassium, and 95 g chloride. To maintain a stable body content, the amount of principal ions lost must equal the amount consumed. During growth and during pregnancy, the amount accreted for tissue formation also must be considered.

### Physiological Functions

Sodium is the predominant cation in fluids outside the cells (extracellular fluid), whereas potassium is the predominant cation in the intracellular fluid. Chloride is the major anion of the extracellular fluid. Sodium plays a central role in regulating body fluid balance and distribution of fluid between the extracellular and intracellular compartments. As sodium is the major osmotically active particle in the extracellular fluid, sodium and its accompanying anion determines the osmolar concentration, or osmolality, of this compartment. An increase in sodium concentration will increase the osmolality of the extracellular fluid, thus causing water to move out of the cells into the extracellular compartment. It will also cause water retention by stimulating the thirst mechanism and by decreasing urine flow. The opposite occurs when sodium concentration is decreased. Thus, sodium plays a central role in regulating body fluid balance and the distribution of fluid between the extracellular and intracellular compartments.

Potassium is necessary for normal growth and plays an important function in cell metabolism, enzyme reactions, and synthesis of muscle protein. Both sodium and potassium are involved in maintaining proper acidity (pH) of the blood and in maintaining nerve and mus-

cle functions. Normal resting membrane potentials of nerve and muscle cells range between  $-50$  and  $100$  mV, with the inside of the cells negative with respect to the outside. These resting membrane potentials are maintained by the chemical gradient of potassium across cell membranes. Activation of excitable cells alters their membrane permeabilities to sodium and potassium, leading to changes in their membrane potentials. A weak stimulus causes a small depolarization (the inside of the cell is made less negative) as a result of sodium influx along its electrochemical gradient via the voltage-gated sodium channels in cell membranes. This is followed by repolarization, which is a manifestation of potassium efflux. If the stimulus is sufficiently strong, large changes in the membrane potential occur, during which the membrane potential may change from  $-70$  mV to  $+30$  mV, and then repolarize back to its resting membrane potential. This action potential, caused by alternation of potassium steady-state potentials with pulsed sodium potentials, gives rise to a traveling wave of depolarization that is conducted along the nerve fiber to exert an effect on the effector cells it innervates (supplies with nerves). In muscles, action potential leads to muscle contraction.

Dietary sodium chloride in foods and beverages is absorbed mostly in the small intestine. Active transport of sodium out of the small intestinal epithelial cells across their basolateral membrane provides an electrochemical gradient for the absorption of sodium across the luminal membrane. Entry of sodium through carrier proteins can either transport other solutes against their concentration gradient in the same direction (co-transport) or in an opposite direction (counter-transport). A number of transporters have receptor sites for binding sodium and glucose, galactose, or amino acids. Therefore, entry of sodium across the luminal membrane also brings in a solute. Counter-transport mechanisms operating in the kidneys allow excess hydrogen and potassium to be excreted in the urine.

### Consumption of Sodium, Chloride, and Potassium

Consumption usually exceeds the needs of an individual, although the amount consumed varies widely with dietary habits. Most natural foods contain high potassium content but are lower in sodium content (Table 1). American adults consume an average of 2.5 to 3.5 g of potassium daily. Individuals consuming large amounts of fruits and vegetables may have a daily intake of as high as 11 g. Sodium is consumed mainly as sodium chloride (table salt). A small amount is consumed as sodium carbonate, sodium citrate, and sodium glutamate. Intakes of sodium vary, averaging 2 to 5 g/day of sodium or 5 to 13 g/day of sodium chloride. Only about 10 percent of sodium intake is from natural foods, the rest from sodium salts added during cooking and at the table, and from salts added during processing of foods. In regions where con-

sumption of salt-preserved foods is customary, intake of sodium can be as high as 14 to 20 g/day.

Under normal circumstances, about 99 percent of dietary sodium, chloride, and potassium is absorbed. Absorption occurs along the entire length of the intestine, the largest fraction being absorbed in the small intestine and the remaining 5 to 10 percent in the colon. Potassium is also secreted in the colon. Various homeostatic regulatory mechanisms, the most important of which is aldosterone, modulate the absorption of sodium and secretion of potassium.

Loss of Sodium, Chloride, and Potassium

Obligatory loss of fluids through skin, urine, and feces invariably causes loss of these ions. Minimal obligatory loss for an adult consuming average intakes has been estimated to be 115 mg/day for sodium and 800 mg/day for potassium. Over 95 percent of loss is in the urine. Under most circumstances, loss of chloride parallels that of sodium. Loss of these ions can increase greatly in diuresis, vomiting, and diarrhea. Loss of sodium chloride can also increase greatly from profuse sweating.

**Recommended Intake.** Daily minimum needs can be estimated from the amount required to replace obligatory

TABLE 2

Estimated minimum requirement across the life cycle			
	Sodium mg/day	Chloride mg/day	Potassium mg/day
Infants			
0-0.5 y	120	180	500
0.5-1.0 y	200	300	700
Children			
1 y	225	350	1000
2-5 y	300	500	1400
6-9 y	400	600	1600
10-18 y	500	750	2000
Adults			
>18 y	500	750	2000

losses (Table 2). The need is increased in infants and children, and during pregnancy and lactation. Estimated safe minimum intake levels are higher than the minimum requirements to account for the various degrees of physical activity of individuals and environmental conditions. Average intakes in the United States are higher than the estimated safe minimum levels of sodium chloride (1.3 g/day) and potassium (2 g/day).

The association of high salt intake with hypertension and the beneficial effects of potassium in hypertension has led to recommendations that daily intake of salt should not exceed 6 g and that of potassium should be increased to 3.5 g. This can be achieved by increasing intake of dietary fruits and vegetables.

Regulation of Sodium, Chloride, and Potassium Balance

Various mechanisms regulate excretion of these ions by the kidneys to maintain homeostatic equilibrium of body fluids. Urinary sodium excretion is controlled by varying the rate of sodium reabsorption from the glomerular filtrate by tubular cells, whereas potassium excretion is controlled by varying the rate of tubular secretion of potassium.

Abnormally low blood volume (hypovolemia) in sodium deficit increases renal sodium chloride reabsorption by increasing sympathetic discharge to the kidneys, and by stimulation of two hormonal systems, the renin-angiotensin-aldosterone and the antidiuretic systems. This results in the production of low urine volume with low sodium and chloride contents. Hypovolemia also initiates the thirst mechanism and increases an appetite for salt (or salt cravings). The presence of salt appetite in animals is to ensure an adequate intake of salt to protect the extracellular fluid volume from excessive loss of sodium due to sweating, diarrhea, pregnancy, or lactation. The development of salt appetite is of signif-

TABLE 1

Food sources of sodium, chloride, and potassium (mg/100 g)			
	Sodium	Chloride	Potassium
Natural Foods			
Beef, lean (ribs, loin)	65	59	355
Pork, lean (ribs, loin)	70	—	285
Chicken fryers (with skin)	83	85	359
Salmon, fresh	48	59	391
Milk (pasteurized, whole cow's)	55	100	139

## DIARRHEA

Daily, about 8 to 10 l of water and large amounts of ions enter the gastrointestinal tract; about 1 to 2 l are from the diet, the rest from secretions of the alimentary tract. The greater part of this fluid is absorbed by the intestinal cells so that only about 150 ml of fluid are lost daily in the stool of an adult. Stools contain a low content of sodium and chloride but a high content of potassium so that the daily losses averages 6 mmol for sodium, 12 mmol for potassium, 3 mmol for chloride, and 5 mmol for bicarbonate. Loss of this water and ions can increase greatly in diarrhea, and if extreme, several liters of fluid can be lost, leading to dehydration and electrolyte and acid-base disturbances.

Diarrhea is defined as an increase in stool liquidity and a fecal volume of more than 200 ml/day in adults. Clinically, the most common and important causes of diarrhea are osmotic and secretory. Ingestion of a poorly absorbable solute, such as magnesium sulfate, or malabsorption or maldigestion of a specific solute because of enzyme deficiencies, as seen in lactase deficiency, can cause osmotic diarrhea. The presence of these solutes increases the intestinal luminal osmolarity, causing water to be retained in the lumen.

Various viral and bacterial infections can cause secretory diarrhea. Enteroinvasive bacteria such as *Shigella* and *Salmonella* invade intestinal mucosa to produce ulceroinflammatory lesions resulting in a failure of normal absorption. On the other hand, bacteria such as *Vibrio cholerae* release toxins that increase secretion of sodium chloride and water. If the cholera is severe, up to 18 l of

watery stools can be passed in a day. These stools contain ionic concentrations similar to that of plasma, so that large amounts of sodium, chloride, and potassium can be lost.

Dehydration caused by diarrhea ranges from mild to severe. The severity of dehydration can be assessed clinically by examining the patient for sunken eyeballs, skin turgor, mental status, blood pressure, and urine output. Fluid replacement is of utmost importance, especially in severe dehydration, to prevent circulatory collapse. Although diarrhea causes losses of sodium as well as potassium and bicarbonate, the immediate concern in treating severe diarrhea is to replace sodium and water to restore the circulatory volume. Dehydration in diarrhea can be reversed by oral or, in emergency, intravenous rehydration therapy.

The World Health Organization has recommended the use of oral rehydration therapy for treatment of mild to moderate cases of diarrhea. This program has been very successful in reducing mortality from diarrheal diseases, particularly in infants in developing countries. Oral rehydration fluid contains 3.5 g of sodium chloride, 2.5 g of sodium bicarbonate, 1.5 g of potassium chloride, and 20 g of glucose in 1 l of water. An alternative household remedy is to make a solution containing three "finger pinches" of salt, a "fistful of sugar" and one quart of water. Addition of sugar to the oral rehydration fluid helps to increase the absorption of sodium chloride through the sodium-glucose transporter system in the small intestine.

icance in the successful adaptation to a terrestrial life, especially in herbivorous animals. The need for salt can be satisfied by providing cattle and sheep with salt licks. Humans and other carnivores are less dependent on separate supplies of salt because dietary salt can be obtained from meat. However, they may develop a craving for salt when they are sodium deficient. This deficit-induced salt craving may be mediated by hormones acting on the brain and by changes in gustatory response. Abnormally high blood volume (hypervolemia) in sodium excess increases renal excretion of sodium chloride by suppression of sympathetic discharge to the kidneys, suppression of the renin-angiotensin-aldosterone and antidiuretic systems, and stimulation of the secretion of atrial natriuretic peptides.

Aldosterone is the most important hormone regulating secretion of potassium. Aldosterone secretion is triggered by angiotensin II, by high plasma potassium concentration, or by low plasma sodium concentration.

Plasma concentrations of potassium and hydrogen also affect directly the secretion of potassium by the distal nephrons. The rate of potassium secretion parallels the plasma potassium concentration. Secretion of potassium in response to changes in acid-base balance (which affects plasma pH) is complex. In general, acute acidosis decreases secretion of potassium, whereas acute alkalosis increases secretion and loss of potassium from the body. Response to chronic acid-base disorders is varied.

### Sodium, Chloride, and Potassium Imbalance

Acute excessive intakes do not normally result in retention of sodium, chloride, and potassium because of the capacity of the kidneys to excrete these ions. Retention occurs when kidney function is compromised. Dietary deficiency does not normally occur because normal consumption usually exceeds body needs.

## THERMOREGULATION THROUGH PERSPIRATION

Heat is produced continuously by the body during metabolism, and it is also taken up by the body from the environment by radiation and conduction. Heat is lost from the body by radiation, conduction and convection, and evaporation. Even in the absence of perspiration, water is lost continuously from the body by evaporation from the upper respiratory tract and by passive evaporation from the skin. These insensible water losses amount to a total of about 0.6 l/day, of which slightly more than 50 percent is from the skin. For every liter of water that evaporates from the body, 580 kcal (2428 kJ) of heat is dissipated. During intense physical exertion or at a high ambient temperature, loss of heat from radiation, conduction, and insensible water loss are insufficient to prevent a rise in body temperature. Under these circumstances, heat loss is enhanced by the production and evaporation of sweat. Loss of heat by evaporation of sweat is an effective means of removing excess heat from the body, and it can be controlled by regulating the rate of sweating. When the body temperature rises above 98.6°F (37°C), stimulation of the temperature-regulating center in the hypothalamus causes sweating.

Sweat is produced by sweat glands by actively secreting into ducts a fluid similar in composition to that of plasma. As this primary secretion passes along the ducts of the sweat glands to the surface of the skin, sodium and chloride are absorbed in excess of water, resulting in the production of a dilute fluid that has a lower content of sodium and chloride. Sodium chloride content in sweat varies; it depends on the rate of flow. For a young adult, the average value is about 50 mmol/l for sodium and 30 mmol/l for chloride. The transport mechanisms for sodium and chloride are affected in patients suffering from cystic fibrosis so that their concentrations in the sweat are increased. For the purpose of diagnosis, the upper limit of the normal values for children and young adults are set at 70–80 mmol/l for sodium and 60–70 mmol/l for chloride (Lentner, ed.).

Rate of sweat production depends on the ambient temperature and humidity, and the degree of activity of

the individual. For a 70 kg man doing light work at an ambient temperature of 84°F (29°C), daily loss is about 2 to 3 l. An unacclimatized individual who is performing hard physical activity in a hot, humid environment may lose, for a short time, up to 2 to 4 l/hour of sweat. As the duration of perspiration increases, the rate of production decreases to about 0.5 l/hour. Therefore, even at maximal sweating, the rate of heat loss may not be rapid enough to dissipate the excess heat from the body. Dehydration from excessive loss of water and sodium chloride stimulates the thirst mechanism, and if water intake is not increased, it can cause weakness and, if severe, circulatory collapse.

Adaptation to heat leads to physiological changes that include an increase in sweat production, an increase in plasma volume, and a decrease in concentration of sodium and chloride in the sweat and urine. These latter two effects are caused by an increase in aldosterone secretion as a result of dehydration and loss of sodium from the body. The decrease in the concentration of sodium and chloride in sweat and urine allows for better conservation of these ions in the body. An unacclimatized person who sweats profusely often loses as much as 13 to 30 g of salt per day for the first few days, but after four to six weeks of acclimatization the loss can be as low as 3 to 5 g a day.

There is a limit at which the body can lose heat even when perspiring maximally. The progressive rise in body temperature will affect the heat-regulating ability of the hypothalamus, resulting in a decrease in sweating. Therefore, a high body temperature tends to perpetuate itself unless measures are taken specifically to decrease the body temperature. When the body temperature rises beyond a critical temperature of 106°F (41°C), the person is likely to develop heat stroke. Symptoms include dizziness, abdominal distress, delirium, and eventually loss of consciousness. Some of these symptoms are exacerbated by a mild degree of circulatory shock as a result of sodium loss and dehydration.

Since the extracellular fluid volume changes in parallel with its sodium concentration, sodium retention in renal failure or congestive heart failure results in edema and possibly hypertension (Table 3). Excessive loss of sodium resulting in hypovolemia and hypotension can occur through diuresis, Addison's disease, severe vomiting, or diarrhea.

Changes in plasma concentration of potassium affects the excitability of nerves and muscle cells (Table 3). Re-

tention of potassium causes hyperkalemia (plasma potassium concentration exceeding 5.0 mmol/l), and depletion causes hypokalemia (plasma potassium concentration less than 3.5 mmol/l). Retention of potassium occurs when there is a lack of aldosterone secretion, or a lack of responsiveness of the kidney to aldosterone. An important clinical manifestation of hyperkalemia is cardiac arrhythmia, which can lead to cardiac arrest. Depletion of potassium can occur through hyperaldosteronism, diuresis,

TABLE 3

**Imbalance of sodium and potassium**

Primary defect	Pathological causes	Clinical manifestation
sodium retention	congestive heart failure renal failure Conn's syndrome	edema, hypertension
sodium depletion	excessive perspiration Addison's disease diuretic therapy renal diseases prolonged vomiting diarrhea	orthostatic hypotension, muscular weakness and cramps, dizziness and syncope, circulatory shock
potassium retention	aldosterone deficiency	cardiac arrhythmias leading to cardiac arrest
potassium depletion	wasting diseases and starvation hyperaldosteronism metabolic alkalosis diuretic therapy renal diseases prolonged vomiting diarrhea	muscle weakness, impairment of neuromuscular function, cardiac arrhythmias

SOURCE: Palmer, Alpern, and Seldin; Rodriguez-Soriano; Toto and Seldin.

vomiting, or diarrhea. Manifestations of hypokalemia include depressed neuromuscular functions and, in more severe hypokalemia, cardiac arrhythmias.

### Nutritional Considerations

Epidemiological and experimental evidence has implicated habitual high dietary salt consumption in the development of hypertension, but controversy remains regarding the importance of sodium salts in the regulation of blood pressure and the mechanisms by which salt influences blood pressure (Stamler, 1977). Intervention studies of dietary salt restrictions to lower blood pressure have produced mixed results. Nevertheless, various clinical trials indicate some beneficial effects of dietary restriction of sodium on blood pressure, and it may also decrease the incidence of stroke and ischemic heart disease.

High consumption of potassium, found in foods like oranges, apricots, and dates, on the other hand, appears to have a protective action against cardiovascular diseases, although the mechanism of action is not known. Epidemiological studies have demonstrated an inverse relationship of potassium intake with blood pressure, incidence of stroke, and other cardiovascular diseases (Young, Huabao, and McCabe). A direct relationship between blood pressure and the ratio of sodium to potassium in the urine has also been found (Stamler).

Repeated intake over a long period of salt from salted and smoked products is associated with atrophic gastritis and gastric cancer. However, experimental evidence indicates that salt alone is not carcinogenic; the high di-

etary salt content may enhance the initiation of cancer by facilitating the action of any carcinogen, such as polycyclic aromatic hydrocarbons, present in the diet (Cohen and Roe, 1977), or potentiating *Helicobacter pylori*-associated carcinogenesis (Fox et al., 1999).

Hwai-Ping Sheng

**ENERGY.** Sufficient dietary energy is essential to the survival and health of all animals. For understanding the biology and health of humans, energy is particularly important for a number of reasons. First, food and energy represent critical points of interaction between humans and their environment. The environments in which humans live determine the range of food resources that are available and how much energy and effort are necessary to procure those resources. Indeed, the dynamic between energy intake and energy expenditure is quite different for a subsistence farmer of Latin America than it is for

an urban executive living in the United States. Beyond differences in the physical environment, social, cultural, and economic variation also shape aspects of energy balance. Social and cultural norms are important for shaping food preferences, whereas differences in subsistence behavior and socioeconomic status strongly influence food availability and the effort required to obtain food.

Additionally, the balance between energy expenditure and energy acquired has important adaptive consequences for both survival and reproduction. Obtaining sufficient food energy has been an important stressor throughout human evolutionary history, and it continues to strongly shape the biology of traditional human populations today.

This article examines aspects of energy expenditure and energy intake in humans. How energy is measured is first considered, with a look at how both the energy content of foods and the energy requirements for humans are determined. Next, aspects of energy consumption and the chemical sources of energy in different food items are examined. Third, the physiological basis of variation in human energy requirements is explored, specifically a consideration of the different factors that determine how much energy a person must consume to sustain him- or herself. Finally, patterns of variation in energy intake and expenditure among modern human populations are examined, with the different strategies that humans use to fulfill their dietary energy needs highlighted.

### **Calorimetry: Measuring Energy**

The study of energy relies on the principle of calorimetry, the measurement of heat transfer. In food and nutrition, energy is most often measured in kilocalories (kcal). One kilocalorie is the amount of heat required to raise the temperature of 1 kilogram (or 1 liter) of water 1°C. Thus, a food item containing 150 kilocalories (two pieces of bread, for example) contains enough stored chemical energy to increase the temperature of 150 liters of water by 1°C. Another common unit for measuring energy is the joule or the kilojoule (1 kilojoule [kJ] = 1,000 joules). The conversion between calories and joules is as follows: 1 kilocalorie equals 4.184 kilojoules.

To directly measure the energy content of foods, scientists use an instrument known as a bomb calorimeter. This instrument burns a sample of food in the presence of oxygen and measures the amount of heat released (that is, kilocalories or kilojoules). This heat of combustion represents the total energetic value of the food.

Basic principles of calorimetry are also used to measure energy expenditure (or requirements) in humans and other animals. Techniques for measuring energy expenditure involve either measuring heat loss directly (direct calorimetry) or measuring a proxy of heat loss such as oxygen consumption (O<sub>2</sub>) or carbon dioxide (CO<sub>2</sub>) production (indirect calorimetry). Direct calorimetry is done under controlled laboratory conditions in insulated chambers that measure changes in air

temperature associated with the heat being released by a subject. Although quite accurate, direct calorimetry is not widely used because of its expense and technical difficulty.

Thus, methods of indirect calorimetry are more commonly used to quantify human energy expenditure. The most widely used of these techniques involve measuring oxygen consumption. Because the body's energy production is dependent on oxygen (aerobic respiration), O<sub>2</sub> consumption provides a very accurate indirect way of measuring a person's energy expenditure. Every liter of O<sub>2</sub> consumed by the body is equivalent to an energy cost of approximately 5 kilocalories. Consequently, by measuring O<sub>2</sub> use while a person is performing a particular task (for example, standing, walking, or running on a treadmill), the energy cost of the task can be determined.

With the Douglas bag method for measuring O<sub>2</sub> uptake, subjects breathe through a valve that allows them to inhale room air and exhale into a large collection bag. The volume and the O<sub>2</sub> and CO<sub>2</sub> contents of the collected air sample are then measured to determine the total amount of oxygen consumed by the subject. Recent advances in computer technology allow for the determination of O<sub>2</sub> consumption more quickly without having to collect expired air samples. One computerized system for measuring oxygen consumption, like the Douglas bag method, determines energy costs by measuring the volume and the O<sub>2</sub> and CO<sub>2</sub> concentrations of expired air samples.

### **Sources of Food Energy**

The main chemical sources of energy in our foods are carbohydrates, protein, and fats. Collectively, these three energy sources are known as macronutrients. Vitamins and minerals (micronutrients) are required in much smaller amounts and are important for regulating many aspects of biological function.

Carbohydrates and proteins have similar energy contents; each provides 4 kilocalories of metabolic energy per gram. In contrast, fat is more calorically dense; each gram provides about 9 to 10 kilocalories. Alcohol, although not a required nutrient, also can be used as an energy source, contributing 7 kcal/g. Regardless of the source, excess dietary energy can be stored by the body as glycogen (a carbohydrate) or as fat. Humans have relatively limited glycogen stores (about 375–475 grams) in the liver and muscles. Fat, however, represents a much larger source of stored energy, accounting for approximately 13 to 20 percent of body weight in men and 25 to 28 percent in women.

The largest source of dietary energy for most humans is carbohydrates (45–50 percent of calories in the typical American diet). The three types of carbohydrates are monosaccharides, disaccharides, and polysaccharides. Monosaccharides, or simple sugars, include glucose, the body's primary metabolic fuel; fructose (fruit sugar); and

galactose. Disaccharides, as the name implies, are sugars formed by a combination of two monosaccharides. Sucrose (glucose and fructose), the most common disaccharide, is found in sugar, honey, and maple syrup. Lactose, the sugar found in milk, is composed of glucose and galactose. Maltose (glucose and glucose), the least common of the disaccharides, is found in malt products and germinating cereals. Polysaccharides, or complex carbohydrates, are composed of three or more simple sugar molecules. Glycogen is the polysaccharide used for storing carbohydrates in animal tissues. In plants, the two most common polysaccharides are starch and cellulose. Starch is found in a wide variety of foods, such as grains, cereals, and breads, and provides an important source of dietary energy. In contrast, cellulose—the fibrous, structural parts of plant material—is not digestible by humans and passes through the gastrointestinal tract as fiber.

Fats provide the largest store of potential energy for biological work in the body. They are divided into three main groups: simple, compound, and derived. The simple or “neutral fats” consist primarily of triglycerides. A triglyceride consists of two component molecules: glycerol and fatty acid. Fatty acid molecules, in turn, are divided into two broad groups: saturated and unsaturated. These categories reflect the chemical bonding pattern between the carbon atoms of the fatty acid molecule. Saturated fatty acids have no double bonds between carbons, thus allowing for the maximum number of hydrogen atoms to be bound to the carbon (that is, the carbons are “saturated” with hydrogen atoms). In contrast, unsaturated fatty acids have one (monounsaturated) or more (polyunsaturated) double bonds. Saturated fats are abundant in animal products, whereas unsaturated fats predominate in vegetable oils.

Compound fats consist of a neutral fat in combination with some other chemical substance (for example, a sugar or a protein). Examples of compound fats include phospholipids and lipoproteins. Phospholipids are important in blood clotting and insulating nerve fibers, whereas lipoproteins are the main form of transport for fat in the bloodstream.

Derived fats are substances synthesized from simple and compound fats. The best known derived fat is cholesterol. Cholesterol is present in all human cells and may be derived from foods (exogenous) or synthesized by the body (endogenous). Cholesterol is necessary for normal development and function because it is critical for the synthesis of such hormones as estradiol, progesterone, and testosterone.

Proteins, in addition to providing an energy source, are also critical for the growth and replacement of living tissues. They are composed of nitrogen-containing compounds known as amino acids. Of the twenty different amino acids required by the body, nine (leucine, isoleucine, valine, lysine, threonine, methionine, phenylalanine, tryptophan, and histidine) are known as “essential” because they cannot be synthesized by the body and

thus must be derived from food. Two others, cystine and tyrosine, are synthesized in the body from methionine and phenylalanine, respectively. The remaining amino acids are called “nonessential” because they can be produced by the body and need not be derived from the diet.

### Determinants of Daily Energy Needs

A person’s daily energy requirements are determined by several different factors. The major components of an individual’s energy budget are associated with resting or basal metabolism, activity, growth, and reproduction. Basal metabolic rate (BMR) represents the minimum amount of energy necessary to keep a person alive. Basal metabolism is measured under controlled conditions while a subject is lying in a relaxed and fasted state.

In addition to basal requirements, energy is expended to perform various types of work, such as daily activities and exercise, digestion and transport of food, and regulating body temperature. The energy costs associated with food handling (i.e., the thermic effect of food) make up a relatively small proportion of daily energy expenditure and are influenced by amount consumed and the composition of the diet (e.g., high-protein meals elevate dietary thermogenesis). In addition, at extreme temperatures, energy must be spent to heat or cool the body. Humans (unclothed) have a thermoneutral range of 25 to 27°C (77–81°F). Within this temperature range, the minimum amount of metabolic energy is spent to maintain body temperature. Finally, during one’s lifetime, additional energy is required for physical growth and for reproduction (e.g., pregnancy, lactation).

In 1985 the World Health Organization (WHO) presented its most recent recommendations for assessing human energy requirements. The procedure used for determining energy needs involves first estimating BMR from body weight on the basis of predictive equations developed by the WHO. These equations are presented in Table 1. After estimating BMR, the total daily energy expenditure (TDEE) for adults (18 years old and above) is determined as a multiple of BMR, based on the individual’s activity level. This multiplier, known as the physical activity level (PAL) index, reflects the proportion of energy above basal requirements that an individual spends over the course of a normal day. The PALs associated with different occupational work levels for adult men and women are presented in Table 2. The WHO recommends that minimal daily activities such as dressing, washing, and eating are commensurate with a PAL of 1.4 for both men and women. Sedentary lifestyles (e.g., office work) require PALs of 1.55 for men and 1.56 for women. At higher work levels, however, the sex differences are greater. Moderate work is associated with a PAL of 1.78 in men and 1.64 in women, whereas heavy work levels (for example, manual labor, traditional agriculture) necessitate PALs of 2.10 and 1.82 for men and women, respectively.

TABLE 1

Equations for predicting basal metabolic rate (BMR) based on body weight (Wt in kilograms)		
Age (years)	BMR (kcal/day)	
	Males	Females
0–2.9	60.9 (Wt) – 54	61.0 (Wt) – 51
3.0–9.9	27.7 (Wt) + 495	22.5 (Wt) + 499
10.0–17.9	17.5 (Wt) + 651	12.2 (Wt) + 746
18.0–29.9	15.3 (Wt) + 679	14.7 (Wt) + 496
30.0–59.9	11.6 (Wt) + 879	8.7 (Wt) + 829
60+	13.5 (Wt) + 487	10.5 (Wt) + 596
SOURCE: FAO/WHO/UNU, 1985		

In addition to the costs of daily activity and work, energy costs for reproduction also must be considered. The WHO recommends an additional 285 kcal/day for women who are pregnant and an additional 500 kcal/day for those who are lactating.

Energy requirements for children and adolescents are estimated differently because extra energy is necessary for growth and because relatively less is known about variation in their activity patterns. For children and adolescents between 10 and 18 years old, the WHO recommends the use of age- and sex-specific PALs. In contrast, energy requirements for children under 10 years old are determined by multiplying the child’s weight by an age- and sex-specific constant. The reference values for boys and girls under 18 years old are presented in Table 3.

Human Variation in Sources of Food Energy

Compared to most other mammals, humans are able to survive and flourish eating a remarkably wide range of foods. Human diets range from completely vegetarian (as observed in many populations of South Asia) to those based almost entirely on meat and animal foods (for example, traditional Eskimo/Inuit populations of the Arctic). Thus, over the course of evolutionary history, humans have developed a high degree of dietary plastic-

ity. This ability to utilize a diverse array of plant and animal resources for food is one of the features that allowed humans to spread and colonize ecosystems all over the world.

Table 4 presents information on per capita energy intakes and the percentage of energy derived from plant and animal foods for subsistence-level (i.e., food-producing) and industrial human societies. The relative contribution of animal foods varies considerably, ranging from less than 10 percent of dietary energy in traditional farming communities of tropical South America, to more than 95 percent among traditionally living Inuit hunters of the Canadian Arctic.

Subsistence-level agricultural populations, as a group, have the lowest consumption of animal foods. Among hunting and gathering populations, the contribution of animal foods to the diet is variable, partly reflecting the environments in which these populations reside. For example, the !Kung San, who live in arid desert environments of southern Africa, have among the lowest levels of animal food consumption among hunter-gatherers. In contrast, hunters of the Arctic rely almost entirely on animal foods for their daily energy. Foragers living in forest and grassland regions of the tropics (for example, the Ache and the Hiwi) have intermediate levels of animal consumption.

Regardless of whether they are from plant or animals, the staple foods in most human societies are calorically dense. Indeed, one of the hallmarks of human

evolutionary history has been humankind's success at developing subsistence strategies that maximize the energy returns from available food resources. The initial evolution of human "hunting and gathering" economies some 2 million years ago is an example of this. By incorporating more meat into their diet, man's hominid ancestors were able to increase the energy contents of their diets.

With the evolution of agriculture, human populations began to manipulate relatively marginal plant species so as to increase their productivity, digestibility, and energy content. Today, staple agricultural crops such as rice, wheat, and other cereal grains are calorically dense (more than 300 kilocalories per 100 grams), and are much richer sources of energy than the wild plants from which they evolved.

Novel methods of food processing also allow humans to increase the energy content and digestibility of their foods. The most fundamental of these techniques is the use of fire for cooking, a strategy adopted by man's hominid ancestors at least 400,000 years ago. Cooking makes plant foods more digestible by helping to break down complex carbohydrates. Recent work has shown that cooking can increase the energy content of starchy tubers (potatoes, cassava) by more than 70 percent.

Another interesting example of processing food to raise its energy content is seen among populations living in the high Andes of South America. Here, small potatoes are left outside for several days to be repeatedly frozen during the cold nights and then dried under the intense daytime sun. The resulting product, called *chuño*, can be stored for many months and has an energy content more than three times that of a fresh potato (330 kilocalories per 100 grams versus 90 kilocalories per 100 grams).

## Human Variation in Energy Expenditure

Humans also show considerable variation in levels of energy expenditure. Recent work by Allison E. Black and colleagues indicates that daily energy expenditure in human groups typically ranges from 1.2 to 5.0 times BMR (i.e., PAL = 1.2–5.0). The lowest levels of physical activity, PALs of 1.20 to 1.25, are observed among hospitalized and nonambulatory populations. In contrast, the highest levels of physical activity (PALs of 2.5–5.0) have been observed among elite athletes and soldiers in combat training. Within this group, Tour de France cyclists have the highest recorded daily energy demands of 8,050 kcal/day (a PAL = 4.68)!

Table 5 presents data on body weight, total daily energy expenditure, and PALs of adult men and women from selected human groups. Men of the subsistence-level populations (that is, foragers, pastoralists, and agriculturalists) are, on average, 20 kilograms (45 pounds) lighter than their counterparts from the industrialized world, and yet have similar levels of daily energy expenditure (2,897 versus 2,859 kcal/day). The same pattern is true for women; those from subsistence-level populations are 12.5 kilograms (28 pounds) lighter than women of industrialized societies, but have higher levels of daily energy expenditure (2,227 versus 2,146 kcal/day).

Thus, daily energy needs are expressed relative to BMR; it is found that adults living a "modern" lifestyle in the industrialized world have significantly lower physical activity levels than those living more "traditional" lives. Among men, PALs in the industrialized societies average 1.67 (range = 1.53 to 1.84), as compared to 1.90 (range = 1.58 to 2.38) among the subsistence-level groups. Physical activity levels among women average 1.63 in the industrialized world (range = 1.48 to 1.69) and 1.78 (range = 1.56 to 2.03) among the subsistence-level societies.

The differences in daily energy demands between subsistence-level and industrialized populations are further highlighted in Figure 1, which shows daily energy expenditure (kilocalories/day) plotted relative to body weight (in kilograms). The two lines denote the best-fit regressions for both groups. These regressions show that at the same body weight, adults of the industrialized world have daily energy needs that are 600 to 1,000 kilocalories lower than those of people living in subsistence-level societies.

It is these declines in physical activity and daily energy expenditure associated with "modern" lifestyles that are largely responsible for the growing problem of obesity throughout the world. In the United States, rates of obesity have increased dramatically over the last twenty years, such that now over half of the adult American population is either overweight or obese. Equally disturbing has been the emergence of obesity as a problem in part of the developing world where it was virtually unknown less than a generation ago. In some sense, obesity and other chronic diseases of the modern world (diabetes and

cardiovascular disease, for example) represent a continuation of trends that started early in man’s evolutionary history. Humans have developed a diet that is extremely rich in calories while at the same time minimizing the amount of energy necessary for physical work and activity. Ongoing work in nutritional science is attempting to better understand the biological and environmental factors that influence patterns of energy consumption and expenditure to promote human health and well-being.

## ENTERAL AND PARENTERAL NUTRITION.

The ascent of enteral and parenteral nutrition into a major therapeutic advance in the clinical care of critically ill patients as well as those with temporary or permanent loss of gastrointestinal function only occurred during the last thirty years of the twentieth century. Enteral tube feeding was first employed in the 1600s and was made popular in the medical profession by the famous English surgeon John Hunter at the end of the eighteenth century.

Three important developments accelerated the widespread acceptance of invasive feeding by tubes in the gastrointestinal tract (enteral nutrition) or in veins (parenteral nutrition). Milton Winitz and his colleagues developed chemically defined diets that provided all the essential nutrients in their predigested form. Protein and carbohydrates were provided as their basic building blocks, amino acids and glucose, with minimal amounts of fat sufficient only to meet basic requirements along

with all the essential vitamins and minerals. Originally intended as low-residue diets for the American space program, they were made available, particularly by Henry Randall, via a feeding tube to surgical patients who could not be nourished with regular food by mouth. Later formulas were made more complex with protein present as peptides, which contain a number of linked amino acids, more complex carbohydrates, and larger amounts of fat. Subsequently Stanley Dudrick, Douglas Wilmore, Harry Vars, and Jonathan Rhoads administered similar predigested nutrients in concentrated form into large veins of six beagle puppies, who tolerated them well and experienced normal growth and development. Similar successes in a human infant and in malnourished surgical patients with gastrointestinal dysfunction led to widespread adoption of this life-saving and sustaining technique. Parenteral fat became available for intravenous administration as a component of parenteral formulas several years later. Finally, scientists recognized that protein calorie malnutrition (PCM) affected from one-quarter to one-half of all hospitalized adults and children (Bistrian et al., 1974; Bistrian et al., 1976), that PCM had a major impact on morbidity and mortality from an underlying disease, and that nutritional support by enteral or parenteral means could improve outcomes in malnourished or stressed individuals.

Initially a few interested individuals employed these techniques mainly in academic centers. However, enteral and parenteral nutrition have become essential components of care in critical care units, important adjuncts for many patients recovering from major abdominal surgery, and lifesaving methods for tens of thousands of individuals with permanent impairments of intestinal functions.

During the late twentieth century investigators developed a greater understanding of why PCM occurs, better methods and formulas for providing enteral and parenteral nutrition, and improved techniques for identifying the patients most likely to benefit. Whereas primary PCM develops as a consequence of inadequate intake of protein, energy, and often other essential nutrients, the PCM seen in hospitalized patients is largely due to the underlying primary disease. A process named the systemic inflammatory response develops following any major tissue injury, infection, or inflammatory disorder, such as inflammatory bowel disease or rheumatoid arthritis, and is a part of the body's innate defense system that supports the immune system and fosters healing. However, the response has potentially harmful side effects, including muscle wasting and severe PCM, if it is prolonged or severe, as when anorexia and gastrointestinal dysfunction limit the spontaneous dietary intake of food and increase the protein breakdown that are parts of the systemic inflammatory response.

The well-nourished individual can tolerate up to one week of illness without requiring invasive nutrition to avoid complications, usually infections or poor wound healing, from PCM. When malnutrition is a problem at

the outset, feeding is helpful within three to five days. In the severely malnourished patient, defined by an unintentional weight loss of 20 percent or more, or the severely ill patient, especially one with a closed head injury, a major skeletal trauma, severe body burns, or a severe infection, feeding begun early can improve the outcome. The American Society for Parenteral and Enteral Nutrition developed specific guidelines for the roles of enteral and parenteral feeding that incorporate these principles (Klein et al.).

An important recognition that feeding critically ill patients, particularly if done incorrectly, could be harmful soon followed its broader application. The primary complications of parenteral nutrition include lung collapse, vein clots, infections related to the tube or as a consequence of poorer blood sugar control, or metabolic complications related to introducing all essential nutrients directly into a vein without modification by the gastrointestinal tract and the liver. With enteral nutrition the primary complication is intestinal intolerance as reflected in vomiting, diarrhea, or aspiration pneumonia. Although some have asserted that enteral feeding is more efficacious than parenteral feeding, a close look at the evidence suggests that they are probably equally effective but that enteral feeding would be preferred whenever possible. The potential complications of both modes of feeding can be minimized by assuring that trained, skilled individuals and teams use them only when indicated.

Subsequent developments included immune-enhancing diets with oils, such as fish oil and certain vegetable oils like flaxseed, containing omega-3 fatty acids; the amino acids arginine and glutamine; and nucleotides. Usually provided in combination, these nutrients, when added to a standard enteral formula, seem to improve outcomes by reducing infection rates and shortening hospital stays after major abdominal surgery for malnourished patients, patients with major traumas or burns, and patients in critical care units (Beale et al.). In addition the placement of feeding tubes by endoscope dramatically increased the number of patients who can receive enteral feeding. Placement into the upper small bowel improves tolerance to enteral feeding among critically ill patients, and placement into the stomach or small bowel with exit of the tube through the abdominal wall avoids surgical placement in less severely ill patients who need chronic feeding. The development and wide application of enteral and parenteral feeding was one of the major medical advances of the twentieth century.

**ENVIRONMENT.** People farm Earth's biosphere to produce food for the sustenance of the human species. Thus, human food systems are part of Earth's complex ecological systems. All of these systems begin with interactions with the sun, which is the ultimate energy source. Sunlight enables plants to manufacture carbohydrates through the process of photosynthesis, in which chlorophyll converts sunlight into chemical energy, synthesizing organic compounds from inorganic compounds. Plants take carbon dioxide, water, and inorganic elements for this conversion process from the air and soil. Humans obtain their nourishment directly from plants, or from animals nourished directly or indirectly by plants. Thus humans ultimately rely on air, soil, water, and sunlight for sustenance.

Humankind has a strong interest in not fouling the environment, as contaminants in the air, water, or soil can end up in the plants that people or their food animals eat. An extreme example of such contamination was the 1986 Chernobyl nuclear power plant explosion in the Ukraine. Although hundreds of thousands of people fled the area that was immediately affected by the explosion, as many as three million people still live in contaminated areas in this farming region. As a result of the ecological devastation from this disaster, enormous amounts of money have been and continue to be spent in an effort to relocate communities and decontaminate the rich farmland.

#### Environmental Progress and Challenges for Agriculture

Agriculture and food systems play a major role in the ecological health of Earth, including the number and

### URBANIZATION AND DEVELOPMENT: THE GREATEST THREAT TO AGRICULTURAL LAND IN THE UNITED STATES

Between 1992 and 1997 more than 3.2 million acres of prime farmland were converted to developed land, at an average rate of 645,000 acres of prime farmland per year. From 1982 to 1997 approximately 30 percent of newly developed lands were converted prime farmland. Conversion of farms and farmland to the scattered and fragmented development of "urban sprawl" also causes the loss and fragmentation of other farm, pasture, and rangelands, as well as forests, wetlands, and other important habitats.

In *Farming on the Edge*, A. Ann Sorenson and others reported that 21 percent of prime or unique farmland conversions occurred in twenty major land resource areas that make up 7 percent of the U.S. land base. These most threatened land resource areas are part of or adjacent to expanding population centers and produce some of the highest value agricultural crops and products.

Shorelands and wetlands lose the buffering provided by farm- and forestlands, and non-point-source pollution from storm water runoff increases. Wetlands are a vital natural resource that provide flood protection and enhance water quality, wildlife habitat, and air quality. According to the 1997 National Resources Inventory, nearly 59 percent of wetland acreage is on forestland and 16.5 percent is on agricultural cropland, pasture, and land in the Conservation Reserve Program.

diversity of life forms that inhabit it. Half of the land mass of the United States, excluding Alaska, is privately owned crop, pasture, and range land. As noted in *America's Private Lands: A Geography of Hope*, the farmers and ranchers who manage these 907 million acres play a key role in maintaining the abundance of these natural resources for present and future generations.

Driven by changing economic and demographic trends, agriculture has become more consolidated, intensified, and specialized. At the same time, there has been increased scientific and public awareness of the detrimental environmental impacts of some agricultural activities, such as the problem of soil erosion. However, by adopting new practices and working with government conservation cost-share and technical-assistance programs, farmers are significantly reducing many of those detrimental impacts. Although soil erosion threatens the future productivity of 29 percent of cultivated acres in

the United States, farmers reduced soil erosion on U.S. farmland by 38 percent from 1982 to 1997. Much of this reduction was accomplished by changing from traditional plowing to no-till or minimum-tillage systems that disturb the soil less and leave a protective layer of crop residue. The United States Department of Agriculture (USDA) programs, such as the Conservation Reserve Program and Wetland Reserve Program, take marginal or fragile croplands out of production and assist landowners with plantings or practices to buffer stream banks and enhance wildlife habitat. Wetlands, including productive yet fragile ecosystems like prairie potholes, have been restored, and the nesting success of ducks has increased.

Many livestock farmers and ranchers have improved grazing management to benefit livestock productivity as well as soil, water, and wildlife resources. For example, the United States and several western European nations are addressing the problem of excess manure in areas with high concentrations of livestock. Farmers are developing nutrient-management plans to make the best use of fertility-building resources in manure and to prevent excessive field applications or run-off into waterways.

Problems with water quality and water supply due to agricultural practices persist in some areas and have recently emerged in others, such as in the northeastern United States, where the water supply has not been a problem historically. Water quality also affects both freshwater and saltwater fisheries (discussed in more detail below). Careful management of agricultural production is critical in maintaining the ecological health of many estuaries (nurseries for fish and shellfish stocks and food webs). Efforts to improve nutrient management and agricultural conservation practices in the extensive watershed of the U.S. Chesapeake Bay are evidence of the growing awareness of the ecological links between farming and fishing.

Developed countries in North America and western Europe use a combination of technical assistance, incentives, and regulatory approaches to address environmental problems associated with agriculture. However, a lack of human and economic resources limits the ability of developing countries to address environmental problems associated with agriculture or other human activities. The clearing of forests in Brazil continues to accelerate in an effort to develop agricultural production for export. Land is cleared for crops and cultivated pasture, much of it to expand livestock and crop production for export markets. The USDA's *Agricultural Baseline Projections* February 2002 report (Westcott) predicted that the conversion of undeveloped land into arable land in Brazil's interior will gain momentum over the next decade. Brazil's share of the world soybean market is projected to grow from 28 to 35 percent by 2011.

In his 2000 Nobel anniversary lecture, agricultural researcher Norman Borlaug noted that irrigated agriculture uses 70 percent of global water withdrawals, covers

17 percent of cultivated land (about 679 million acres), and accounts for 40 percent of world food production.

Loss of genetic diversity in crop plants and livestock—driven by market rewards for high yield, cost-efficiency, and product uniformity—is increasingly recognized as an environmental concern for agriculture. Other concerns include agriculture's effects on biodiversity and health of critical habitats. Working agriculture can be a positive or negative factor in all these areas of environmental concern, depending on local site conditions and management practices.

### World Fisheries and Food Security

Fisheries contribute to world food security, especially since fish are a major source of protein for some of the world's poorest populations. Per capita fish consumption varies among countries, depending on economic wealth, cultural traditions, and fisheries resource base. According to the United Nations Food and Agriculture Organization (FAO), world per capita fish consumption has been increasing since the 1960s, a trend that has been accompanied by increasing incomes. Global trade in fish and shellfish continues to grow and gain importance in developing countries. However, a practice of over-fishing now threatens fisheries around the world. Consumption of fish has been increasing quite dramatically for at least half a century, and stocks have been severely depleted. Too many fish have been harvested with too little thought or provision for protecting the resource base so that it can continue to produce sustainably. U.S. efforts to protect fisheries from over-fishing are showing some results. For example, some long-threatened resources, such as cod and haddock stocks in New England, have begun to recover after decades of decline. However, achieving international cooperation to protect coastal and estuarine environments and to manage and sustain world fisheries remains a challenge.

### Toward a More Sustainable Aquaculture

Aquaculture, often promoted as a solution to over-fishing, has expanded dramatically in Asia for domestic and export markets. As with agriculture, the environmental impacts of aquaculture can vary greatly over the range of management systems and practices. The article "Effect of Aquaculture on World Fish Supplies," by Naylor et al., describes the paradox of aquaculture as both a possible solution and a contributing factor to the collapse of fisheries stocks worldwide.

In the late twentieth and early twenty-first centuries, capture fisheries provided a decreasing share of world food fish, while the share that aquaculture provided surged—nearly tripling from 10 million metric tons in 1987 to 29 million metric tons in 1997. World capture fish harvests leveled off at around 85–95 million metric tons per year, with the catch shifting from larger, higher value carnivorous species of fish to smaller, lower value

### THE AQUACULTURE RUSH IN CHINA

Asia produces 90 percent of the world's aquaculture output, with China alone producing more than two-thirds of the total. Europe, North America, and Japan combined produce just over 10 percent of the total, but these areas consume most of the internationally traded farmed seafood. Excluding mainland China, world fish supplies from aquaculture grew from 3.5 pounds per capita per year in 1991 to 4.7 pounds in 1998. During the same period, according to the United Nations Food and Agriculture Organization (FAO), the per capita supply of aquaculture products in mainland China nearly tripled, growing from 13.2 to 37.4 pounds. Fish consumption in China is strongly correlated with economic growth, and freshwater aquaculture is responding rapidly to market stimulus. Many Chinese aquaculture enterprises are family and cooperative farms, often using integrated multiple-species systems to produce lower value, herbivorous species for household subsistence and local markets. As competition increases for land and water resources, more operations are intensifying, and some are producing higher value carnivorous or omnivorous species such as shrimp for export.

The FAO expects aquaculture to continue to grow in Asia, but it also expects the rate of growth to slow when China becomes a member of the World Trade Organization and thus more open to food imports. China may become a market for cultured fish produced in other Asian countries.

fish used to make feed for farmed fish. Four of the top five capture fish species were used in feed production for the aquaculture and livestock industries.

Alteration of habitat—especially the large-scale transformation of mangroves and coastal wetlands in Asia into fish- and shrimp-farming ponds—also harms wild fish nurseries and the ecological health of coastal wetlands, coral reefs, and related marine habitat. Other factors that diminish wild fisheries are the collection of wild seed stock, food-web interactions (e.g., over-fishing of small fish species that form the food supply for marine predators, including valuable fish species consumed by humans), introduction of exotic species and pathogens, and nutrient pollution from fish farms.

Aquaculturists farm more than 220 species of finfish, shellfish, and crustaceans. Raising carnivorous species such as salmon, which consume wild fish for feed

(producing one pound of farm-raised salmon takes eight pounds of wild fish), can create problems such as interbreeding of wild fish with escaped farmed fish. But some aquaculture benefits estuarine and marine ecosystems, such as filter-feeding oysters, mussels, clams, and some carp, all of which help purify water. A range of fish and shellfish farming systems are being developed for different species, locations, and conditions. Naylor et al. (pp. 1021–1023) offered four primary goals for the sustainability and continued growth of the aquaculture industry: (1) expand farming of smaller, lower feeding-level fish; (2) reduce use of fish meal and fish oils in feed; (3) develop integrated farming systems; (4) promote environmentally sound aquaculture practices and resource management.

### **Food and Ecosystems: Linked since the Rise of Civilization**

Humans have always interacted with their environment in order to obtain food. Local ecosystem characteristics, such as the types and quantities of edible plants and plants eaten by food-producing animals, have significantly affected the evolution and development of human societies and cultures. In his Pulitzer-Prize-winning book *Guns, Germs, and Steel: The Fates of Human Societies*, Jared Diamond traced many of the outcomes of human history, including the comparative advantages of different societies and the availability and relative abundance of different types of plants and animals. For example, a hospitable growing environment with deep, fertile soil, adequate rainfall, and moderate temperatures provides people with a food-producing advantage. (Examples are the traditional “breadbasket” regions of the world: the midwestern United States, the pampas of South America, the plains of central Europe and the Ukraine, and China’s river valleys.) However, through ingenuity, skill, and careful stewardship of resources, humans have produced ample food supplies in challenging environments such as the mountains of Switzerland, the Nile Valley, and arid parts of Australia.

In his book, Diamond also links the development of civilizations to people’s ability to produce abundant food supplies in an environment. For example, settlements could become permanent only when people no longer had to wander in search of food, and when they learned to protect and replenish the soil so that they did not have to abandon exhausted farming sites. A sustained and ample food supply enabled societies to develop technology, writing, and political systems, all of which advanced agriculture even further. Highly developed farming systems were the cornerstone of the rise of the Roman Empire and the unification of China. The ancient Romans understood, and wrote extensively about, the practice of sustainable agriculture. They improved plants and animals through selective breeding, and they emphasized the use of manure and composts to replenish and enrich the life-giving capacity of farmed soils.

### **Lessons from Famines and Ecological Disasters of the Middle Ages**

Cycles of disaster and famine in medieval Europe offer an instructive study in the interplay of agriculture and the environment. A series of extreme natural disasters including floods, crop failures, and epidemics among humans and livestock culminated in the Great European Famine of the early 1300s. In the mid-fourteenth century, another wave of natural disasters, which included the spread of bubonic plague, resulted in the loss of about one-third of the population of Europe, with death rates as high as 60 percent in some communities. These famines and ecological disasters most likely resulted from a complex combination of causes. Bruce M. S. Campbell discussed several theories about the famines in “Ecology Versus Economics in Late Thirteenth- and Early Fourteenth-Century English Agriculture,” in *Agriculture in the Middle Ages* (pp. 76–97). The floods were most likely part of a period of climate change to cooler, wetter weather, accompanied by storm surges in the North Sea.

Medieval agriculture lacked the dynamism to keep pace with the demands of growing urban populations. In response to food shortages, marginal lands that had been used for livestock, hay, and pasture were now used to raise crops for human consumption. However, reducing livestock numbers not only reduced the quantity of foods produced from animals, but also the supply and use of manure on cropland, which ultimately lessened crop yields.

Lack of technical progress in agriculture, nearly continuous wars, and the extractive feudal economic system made the bad situation worse. Campbell explained (p. 94) that warfare wreaked ecological havoc on the food and agriculture system through physical destruction of crops, livestock, stock, equipment, and physical structures. Burdensome taxes levied to finance warring armies and the expropriation of stock, crops, equipment, and marketing and transportation systems also weakened the existing agricultural systems.

This pattern of famine during and after periods of war or civil strife, often coinciding with epidemics and disastrous droughts or floods, recurs in most modern famines, such as those afflicting Africa since the 1970s. Modern famines show how the ecological, economic, and social destruction of war disrupts the production and distribution of food and, subsequently, a society’s ability to feed itself.

### **From Renaissance to Agricultural Revolution**

Significant changes in farming systems that began in parts of Europe during the later medieval period brought about major changes in the ecological health and productivity of the land. Farmers began to combine and integrate crops and livestock in ways that promoted soil quality and fertility and that boosted production. They adopted more intensive and flexible crop rotations, as well as new crops such as oats, turnips grown for animal feed, and nitrogen-fixing legumes. These innovations elimi-

nated the need for fallowing (idling) of land, adding further to sustainable production gains. Campbell found (p. 92) that farmers adopted these systems most readily in areas with natural resource advantages, access to markets, or fewer institutional constraints such as feudal servile tenure or common property rights.

The enclosure of common lands across England in the 1700s and early 1800s transformed agriculture and the English landscape. Well over six million acres, or one-fourth of the cultivated acres in England, were converted from communally held and farmed lands to lands that were privately owned and managed. This conversion enabled farmers to integrate livestock and crops, using manure and crop rotations to restore and improve depleted lands that were formerly pastured or cultivated continuously. The dramatic gains in productivity and prosperity reflect the key role of private property and free enterprise in resource management.

The large amount of available land in the midwestern and western United States lured families to seek new land when the soil became depleted. As a result of this, President Theodore Roosevelt called for a national sense of duty to the land during a 1908 White House Conservation Conference. However, it was not until the dust bowl disaster of the 1930s that major efforts to protect soil and water finally emerged.

The Agricultural Revolution of 1750–1880 improved yields and adaptation of crops and livestock to local conditions around the world. This period of innovation also set the stage for unprecedented scientific and technical progress in the latter half of the twentieth century. In his Nobel address, Borlaug also noted that in 1940 U.S. farmers produced 56 million tons of corn on 77 million acres of land. In 1999 U.S. farmers produced 240 million tons of corn on 71.7 million acres—a greater than four-fold increase in yield per acre, reaped from hybrid seed, fertilizer, and weed control. The Green Revolution of the 1960s and 1970s applied these techniques to rice, wheat, and other crops in the developing world.

### Biotechnology and Questions for the Future

In a response to critics who questioned the environmental effects of advances in agricultural science and technology, Borlaug noted that without the dramatic gains in yields brought about by those advances, three times as much land of equal quality would have been required to match food production in the world at that time. Much of that additional 4.4 billion acres of land would have to come from more marginal and environmentally fragile lands.

By the late twentieth century, biotechnology was yielding new adaptations of crops and animals for food and medicine. U.S. farmers quickly adopted new genetically modified crops. According to the USDA National Agricultural Statistics Service 2002 report *Crop Production—Prospective Plantings*, U.S. farmers intended to plant genetically modified seed on 74 percent of soybean acreage, 71 percent of cotton, and 32 percent of corn

grown for grain in 2002. Most first-generation genetically engineered varieties were designed to reduce pesticide use or to allow use of more benign chemicals.

Proponents maintain that through biotechnology people will find new ways to increase yields, nutritional and health values, and environmental sustainability of food production. Still, controversy persists about environmental impacts, consumer concerns, and access to the new technology for impoverished people and nations. Some people question the new methods of genetic manipulation on philosophical grounds. Despite his strong support of biotechnology, Borlaug said that national, regional, and world policymakers must resolve serious issues raised by the dominant role of proprietary companies in biotechnology investment and research. He questioned how resource-poor farmers in developing countries could obtain products of biotechnology research and what amount of time product patents should last. Thus, in policymaking processes, societies, governments, and international agencies need to make policy decisions based on credible information about how best to meet human food needs from the land and water while safeguarding valuable resources, ecological integrity, and future productivity.

**EPICURUS.** Epicurus, a Greek philosopher (341–270 B.C.E.), has involuntarily given his name to the fastidious pursuit of pleasure. Born on the Greek island of Samos, Epicurus lived and taught mainly in Athens, where he was a precise contemporary of the playwright Menander. The Epicurean school of philosophy, which he founded, centered on his house and garden in Athens. He and his pupils, who included slaves and women, followed a secluded and austere lifestyle there.

Epicurus taught that the gods have no effect on human affairs, that the universe was created by the random swerve of an atom, and that pleasure is the goal of a happy life. His definition of pleasure is, however, a rather negative one, the removal of disturbance and pain. Since pain is caused by unsatisfied desire, one must reduce one's desires to the minimum. The unavoidable demands of instinct must be satisfied; philosophical study is the best way to conquer all desires beyond that point.

Epicurus is not an ideal choice as a spiritual patron of gastronomes or hedonists. Yet he invited this view of his philosophy with such pronouncements as, "The beginning and root of all good is to make the stomach happy: wisdom and learning are founded on that" (Athenaeus, *Deipnosophists* [Professors at dinner], 546 ff.). The belief that Epicurus favored sensual pleasures can be traced to his contemporaries, and to their understandable misinterpretation of his own words.

**EPIPHANY.** Epiphany (from the Greek word for 'manifestation') is the Christian festival that commemorates the revealing of Jesus Christ to the Gentile world,

Epiphany Parade at Tarpon Springs, Florida, 1990. Epiphany parades are popular among Greek Orthodox Christians, and the event serves as a community focal point among immigrants.

as personified by those “wise men from the east” who came “to worship him” (Matthew 2:1–2). In Britain it has another, more prosaic, name, Twelfth Day, because it falls on 6 January, twelve days after Christmas. Over time, the plain gospel account of this momentous encounter became richly embroidered with learned commentary and loving speculation. The “wise men” stepped from the shadows and were deemed to be three in number, each one a mighty king who knelt in turn to pay homage and present his gift to the greatest king of all. The festival formed the end and climax of the Christmas season, marked by a joyful and elaborate church service and much cheerful celebration, with parties and presents, fine feasting, and a favorite game. In this game, played in many parts of medieval Europe, a mock-king was selected to reign over the party, be toasted by loyal subjects, and, sometimes, enjoy the doubtful privilege of paying for the wine downed in his honor. He was chosen not on merit but by the chance that was hinted at in his official title, “King of the Bean.” A bean had been hidden in a cake, and the lucky man who found it became king of the company. The woman who pulled out the corresponding pea was hailed as his queen.

This traditional game remained popular, but in Britain a variation was developed during the late seventeenth century. Guests still enjoyed their cake, which was dark, dense, packed with dried fruit, and often crowned with almond paste and white icing. However, instead of choosing their king and queen by bean and pea, they drew paper lots. The new custom became a craze, and was elaborated until every slip or card bore the name of some character. Each person present thus had a part to play, and the monarchs mingled with such farcical figures as Sir Tunbelly Clumsy and Miss Flirt, Captain Tearaway, and Lady Racket. The character cards might be home-made or bought at any bakery or toy shop during the Christmas season.

In the eighteenth and early nineteenth centuries, the Twelfth Night cake and characters were enormously enjoyed, so much so that the custom found its way to those parts of America, such as Virginia, that were strongly influenced by British taste.

But the fashion that flared so brightly for a while had burned itself out by the end of the nineteenth century. Twelfth Day became just an ordinary date in the British

calendar, and its cake was absorbed into the Christmas Day festivities. In France, however, and, incidentally, in Louisiana, where French traditions are strong, the Bean King still reigns. Bakery windows display tempting versions of the “Galette des Rois,” made of sweet brioche or puff pastry, and in each a bean or, alternatively, a tiny porcelain baby Jesus, is concealed, a guarantee of instant pleasure for children.

**ESCOFFIER, GEORGES-AUGUSTE.** Georges-Auguste Escoffier (1846–1935) was born in Villeneuve-Loubet in France, a village located between Nice and Cannes. During his lifetime he was proclaimed “the finest cook I ever met” by César Ritz of the world-famous Ritz Hotels. Kaiser Wilhelm of Germany praised Escoffier’s exceptional culinary talent, telling him “I am the emperor of Germany, but you are the emperor of chefs.” Escoffier was more than just a great chef. He is credited with simplifying the complex French haute cuisine of the day—he favored less elaborate dishes, prepared lighter sauces, and used more seasonal ingredients. His reorganization of the professional kitchen eliminated duplication of efforts and resulted in more efficient operation.

Growing up, Escoffier’s chief interest was art; he loved to draw and yearned to be a sculptor. However, his grandfather and his father, who was a blacksmith and also grew tobacco, decided otherwise; they said he needed a trade, and they arranged his apprenticeship at age thirteen in his uncle’s Restaurant Français in Nice.

Photogravure portrait of Escoffier dated 1907. ROUGHWOOD COLLECTION.

At age eighteen, Escoffier was cooking at the Hotel Bellevue in Nice and making an impression on those who ate his food. At nineteen, he became *commis rôti* and then *saucier* at the Petit Moulin Rouge in Paris. At the outbreak of the Franco-Prussian War, Escoffier was drafted into the military and became *chef de cuisine*, first at the headquarters of the general of the Army of the Rhine in Metz, and then for a variety of other regimental commanders. Five years later, he was appointed head chef at the Petit Moulin Rouge, where he fed such dignitaries as the Prince of Wales and Sarah Bernhardt. At the age of thirty, he opened Le Faisan Doré in Cannes.

Escoffier’s experience in the military taught him the importance of preserving food, and he began working on methods of canning meats, vegetables, and sauces, and developed a way to preserve tomato sauce in champagne bottles. In his restaurant cooking, he experimented with techniques for simplifying meals and sauces and encouraged the use of seasonal foods. Other accomplishments included helping to found the successful review *L’Art Culinaire* (Culinary art). In this publication, he reflected on problems of feeding the military, published an item about portable stew for soldiers, and wrote about other artistic and practical matters.

In 1884, César Ritz invited Escoffier to become *chef de cuisine* at the Grand Hotel in Monte Carlo in the winter and at the Grand National in Lucerne in the summer. While at these hotels, he designed many things including serving-dishes, some of which bear his name. In 1885 he published *Le Traité sur l'Art de Travailler les Fleurs en Cire* (Treatise on the art of creating wax flowers). In time, Ritz moved on and managed hotels in Cannes and Baden-Baden, while Escoffier stayed behind and thought more about large, complex kitchens. At this time, he also started collecting, recording, and making available his recipes for cooks and headwaiters to use.

In 1890, César Ritz took over the management of Richard d'Oyly Carte's Savoy Hotel in London and invited Escoffier to develop an elegant restaurant there. The Savoy's restaurant quickly became the delight of its clientele, including the Duke of Orleans, one of the hotel's first royal residents, and the Prince of Wales, a frequent guest. Escoffier and the Savoy became known worldwide, and it was there that Escoffier perfected the codification of French haute cuisine. One of the dishes he invented was *pêche Melba*, created in 1894 for Australian opera diva Nellie Melba, who lived at the hotel while singing at Covent Garden. Another was cherries jubilee, invented three years later to celebrate Queen Victoria's Diamond Jubilee.

Escoffier also wrote many books that became bibles in their field, including *Le Guide Culinaire* (1903), a compendium of about five thousand recipes, *Le Carnet d'Épiqueure* (1911), and *Le Livre des Menus* (1912). In 1920, Escoffier retired to his family home in Monte Carlo where he continued to write many books, including *Le Riz* (1927), *La Morue* (1929), and *Ma Cuisine* (1934). That same year, he was awarded France's Legion of Honor.

**ETHNICITY.** See **National Cuisines, Idea of; United States: Ethnic Cuisines.**

**ETHNOBOTANY.** Ethnobotany is the study of the relationship between people and plants. This interdisciplinary field includes studying plants as wild foods and as agricultural crops; as constructs for houses and modes of transportation; as baskets, pottery, and art; as clothing and types of weaving; as medicines and alternative methods for healing; and in the context of cultural myths and religious ceremonies. Research topics address more complex issues, including the cultural consequences of the extinction of a particular plant species on the diet of a culture, impacts of acculturation on a culture's uses of plants, and the transmission of ethnobotanical knowledge from one generation to the next.

Ethnobotanists study all types of cultures, from the past to the present, from indigenous communities in the Amazon Basin to complex plant usage by immigrants in New York City. This field incorporates techniques and research from many fields, especially anthropology, archaeology, biology, botany, chemistry, entomology, geography, history, linguistics, medicine, and zoology.

#### How Does Ethnobotany Study Culture?

Ethnobotanists study culture by examining how plants were used in the past as well as the present. By studying farming practices of the past or examining fossilized plant or human remains, researchers are able to determine what plants were used by ancient civilizations.

Anatomically speaking, modern human beings (*Homo sapiens*) have existed for approximately 150,000 to 200,000 years, but have practiced widespread cultivation for only a fraction of that time. Evidence that agriculture was practiced includes abundant fossilized remains of plants known to have been cultivated or of tools used for preparing soil, cultivating, or harvesting food.

Human skeletons can provide information about the kinds of plants eaten and the ways in which food was pre-

Bora man is shown cooking coca leaves to prepare a paste that he and other members of his tribe will use to enable them to hunt for days without rest and food. © JAY DICKMAN/CORBIS.

## PLANTS THAT STAND BETWEEN SURVIVAL AND STARVATION

There are at least twelve plant species that have had an enormous impact on cultures throughout history. Without them, humankind could not have developed past single a hunting-and-gathering lifestyle.

In the grass family [Poaceae], four plants have been instrumental in the survival of human culture. These plants include wheat (*Triticum aestivum*), which was cultivated more than eleven thousand years ago in the Middle East as a staple grain and today has more than seventeen thousand varieties. Wheat is one of the staple crops of the United States since it is the primary ingredient in bread. Corn (*Zea mays*) was domesticated five thousand years ago in Mexico and Central America and ultimately became dependent on people for its reproduction. Corn has thrived with the assistance of humankind for so long that it can no longer effectively reproduce itself in the wild. Rice (*Oryza sativa*) was cultivated in Southeast Asia by many different cultures as long as five thousand years ago and is a staple in much of Asia and Latin America. Finally, sugar cane (*Saccharum officinarum*) was the staple crop of the indigenous peoples of New Guinea undergoing domestication about five thousand years ago. Nowadays, sugar cane is highly prized as a sweetener.

Two types of potatoes were also considered staples throughout history: the common potato (*Solanum tuberosum*) [Solanaceae] and the sweet potato (*Ipomoea batatas*) [Convolvulaceae]. These tubers actually come from different plant families and are unrelated to each other despite the fact that both are cultivated in South America and both are called potatoes. The common potato was cultivated before 5000 B.C.E. primarily by the multitude of cultures living in the Andean highlands. Hundreds of varieties now exist worldwide. The sweet potato also grows in the mountains, but was more commonly found in the tropical regions of South America and cultivated by Amazonian cultures.

The common bean (*Phaseolus vulgaris*) and the soybean (*Glycine max*)—both members of the Fabaceae bean family—have also been instrumental in the survival of cultures in Latin America and Asia, respectively. Beans were cultivated at least five thousand years ago in Mex-

ico and Peru and often used in combination with corn, providing essential proteins. Soybeans originated in northeast China around the same time and eventually spread worldwide. Soybean production has now shifted from China to the United States, where more than 52 percent of world production occurs.

Coconuts (*Cocos nucifera*) [Araceae] and bananas (*Musa sapientum*) [Musaceae] are often touted as the world's most perfect foods. Although the origins of coconuts are unclear since their fibrous seeds can float in salt water for more than eighty days, researchers believe this important food plant originated in the Indo-Pacific region or possibly Southeast Asia. Bananas also originated in the tropical regions of the Pacific Islands and Southeast Asia more than five thousand years ago and are rich in potassium. The fruits from both of these plants provide high levels of carbohydrates. Sap from banana plants is used as medicine, while their leaves are used in wrapping food for cooking. The husks from coconuts provide strong fibers for weaving, while the fronds of the trees are used as thatching for homes.

Cassava, also known as yucca or manioc (*Manihot esculenta*) [Euphorbiaceae] is a tuber similar in consistency to the common potato and is very starchy. This plant originated in South America and its cultivation began around 5000 B.C.E. Hundreds of varieties now exist of two different types: bitter cassava that contains poisonous cyanogenetic glycosides and sweet cassava that is sold today in marketplaces around the world. Generally, cultures that were more sedentary raised bitter cassava because they were reliant on one garden and therefore would suffer more if herbivorous predators destroyed their gardens. Seminomadic hunter-gardeners would often plant two or three gardens that they could visit throughout the year so damage to one garden was not felt as sharply.

Perhaps the most recent example of a cultivated and important food plant is the sugar beet (*Beta vulgaris*) [Chenopodiaceae]. Beets were cultivated in the eighteenth and nineteenth centuries in Europe. These tubers contain large amounts of sugar and have long been highly prized in Europe, the Mediterranean, and Russia.

pared. Grasses have a ratio of two stable carbon isotopes (C12 and C13) different from that of most other plants eaten by people. Changes in the ratio of these isotopes in human skeletons over time from grass ratios to that found in grains can indicate a shift to grains as a primary source of food. Similarly, the consumption of large

amounts of grains can be documented by examining patterns of wear on the teeth of archeological skeletons.

### Do Plants Have Cultural Roles?

It is easy to think about plants as being used for food or medicine, or even as a source of technology, for exam-

ple, in the making of spears or blowguns by Amazonian peoples or the furniture in your own house. But, how many people associate a particular plant with a particular culture? Plants had cultural roles in ancient civilizations, are tied to historical events, and can be important identifiers in modern-day cultures.

South and Central American cultures such as the Aztecs, Maya, and the Inca were often associated with particular types of food. For instance, the Aztecs were well known to have cultivated *Amaranth* sp. [Amaranthaceae], a high-protein grain that was considered sacred by its cultivators. The Maya people were linked to the production of corn, as were many other smaller tribes scattered across South and Central America, and Mexico. The Inca were known to cultivate potatoes and quinoa, a high-protein grain that is still grown by the Quechua and Aymara Indians, descendants of the Inca. North American natives used various dye plants to produce unique colors for weavings that symbolized their particular tribe, family, and sometimes their ethnolinguistic identity.

### Plants That Made History

Historically, plants have been known to make or break a culture (see sidebar, Plants That Stand between Survival and Starvation). In addition to plants being food staples in societies, many plants are integrally linked to a culture because they improved or adversely affected its history. The tea tree (*Camelia sinensis*) [Theaceae] has huge cultural significance in many Asian cultures. Elaborate methods to cultivate and prepare tea began in China and later spread to Japan, where the tea ceremony became linked with Zen Buddhist beliefs. Egyptians are credited with inventing paper by pressing together strips of papyrus (*Cyperus papyrus*) [Cyperaceae], but real paper, made by separating plant fibers and matting them together in a thin sheet, was invented by the Chinese using paper mulberry (*Broussonetia papyrifera*) [Moraceae].

A darker side of history includes two plants integrally linked to slavery: cotton (*Gossypium* sp.) [Malvaceae] and sugar cane (*Saccharum officinarum*) [Poaceae]. Both plants were big money crops in the Americas and required significant labor, resulting in the enslavement of many African cultures and their transport to the United States and Central America.

Some may argue that the apple tree (*Malus domestica*) [Rosaceae] also had a hand in shaping world history from the moment Eve took that first bite. Few people realize that the intoxicating drug derived from the opium poppy (*Papaver somniferum*) [Papaveraceae] was one of the main reasons China shut down its borders to all outside trade after the establishment of the People's Republic of China in 1949. Production of the opium poppy has increased in present-day Afghanistan in an effort by terrorist groups to raise money in combatting U.S. military presence. Finally, spice plants in general led Christopher

### IMPORTANT SPICE PLANTS

Common Name	Scientific Name
Anise	<i>Pimpinella anisum</i>
Basil	<i>Ocimum basilicum</i>
Bay leaves	<i>Laurus nobilis</i>
Caraway	<i>Carum carvi</i>
Cardamom	<i>Elettaria cardamomum</i>
Celantro	<i>Coriandrum sativum</i>
Celery	<i>Apium graveolens</i>
Chervil	<i>Anthriscus cereifolium</i>
Chives	<i>Allium schoenoprasum</i>
Coriander	<i>Coriandrum sativum</i>
Cumin	<i>Cuminum cyminum</i>
Dill	<i>Anethum graveolens</i>
Fennel	<i>Foeniculum vulgare</i>
Fenugreek	<i>Trigonella foenumgraecum</i>
Garlic	<i>Allium sativum</i>
Horseradish	<i>Americana rusticana</i>
Leek	<i>Allium porrum</i>
Marjoram	<i>Origanum majorana</i>
Mustard	<i>Brassica alba</i> , <i>B. nigra</i>
Onion	<i>Allium cepa</i>
Oregano	<i>Origanum vulgare</i>
Parsley	<i>Petroselinum crispum</i>
Peppermint	<i>Mentha piperita</i>
Rosemary	<i>Rosmarinus officinalis</i>
Sage	<i>Salvia officinalis</i>
Savory	<i>Satureja hortensis</i>
Shallot	<i>Allium ascalonicum</i>
Spearmint	<i>Mentha spicata</i>
Star anise	<i>Illicium verum</i>
Tarragon	<i>Artemesia dracunculus</i>
Thyme	<i>Thymus vulgaris</i>

Columbus to search for a new trade route to India, but resulted in his discovery of the Americas in 1492.

### The Future of Ethnobotany

The future of ethnobotany lies squarely in conservation of both plant species and the cultures that know how to use them. As scientists who work directly with cultures and their natural resources, ethnobotanists are in a unique position to promote strategies for conservation. Ethnobotanists of the future need to develop methods that empower the people with whom they work.

For much of the last century, ethnobotanists have spent their time documenting uses of plants and in finding ways to apply the knowledge of one culture for the benefit of another. They must look beyond this and find

ways to safeguard the rights and knowledge of the people with whom they study as well as analyze more complex issues relating to interdisciplinary applications of cultural knowledge and uses of plants.

Ethnobotanists must develop methods to convey important information to the communities with which they work, treating indigenous collaborators as coauthors and establishing contracts with communities or tribal groups to ensure that a percentage of any future profits are returned to those cultures which originally held such knowledge.

**ETHNOPHARMACOLOGY.** Although the medicinal uses of plants can be traced to earliest human history and many modern pharmaceuticals are based in botanicals (about 30 percent), Western scientists have been reluctant to extend credibility to the therapeutic potential of plants from other cultures. During the last quarter of the twentieth century, however, attitudes about botanical sources of pharmaceuticals and other medicines shifted dramatically in the West. Renewed interest in plant medicines is substantiated in ethnopharmacology, the study of the chemistry and physiologic actions of (primarily plant) medicines used by native populations. *Ethno* denotes cultural group, and *pharmacology* refers to the science of drug sources, activities, and uses (Etkin, 1996; Rivier and Bruhn, 1979; Rivier and Anton, 1991). Scholarly journals that publish research and reviews on the topic include the *Journal of Ethnopharmacology*, *Pharmaceutical Biology*, *Economic Botany*, *Planta Medica*, *Phytotherapy Research*, and *Fitoterapia*.

Ethnopharmacologists represent diverse academic traditions, most prominently anthropology, pharmacology, and botany, and some commercial domains, including the pharmaceutical industry and the rapidly expanding market for “herbal” (botanical) medicines and

medicinal foods. Given the diversity of contributors to ethnopharmacology, the field has considerable breadth in objectives and approaches. At one end of a continuum, anthropologists and a small percentage of ethnobotanists link the ethnography of health and illness to the chemistry and physiologic action of plant medicines. This extends traditional ethnomedical research that addressed the cultural basis of therapeutics and the social relations of healing and that treated plants largely as cultural objects. Anthropological ethnopharmacology has come to include the biodynamic qualities of plants, to acknowledge that tangible attributes may be as important as symbols in the selection of particular species and the interpretation of their physiologic actions.

This biocultural perspective on ethnopharmacology takes into account that native peoples, like Western scientists, are keen observers of their natural environments who embellish the cultural meaning of plants by marking and managing bitter, wound healing, symptom mediating, and other physical attributes. Yucatec Maya populations, for example, distinguish medicinal from nonmedicinal species (including foods) by smell and taste, noting especially astringent, aromatic, and sweet characteristics. These culturally defined clues not only encode information about which symptoms a particular plant treats best but also juxtapose cultural salience to bioactivity. For example, constituents (polyphenols) present in the plants used by Yucatec Maya for digestive complaints are responsible for both astringent taste and efficacy in the treatment of intestinal disorders (Ankli et al., 1999; Brett and Heinrich, 1999). Anthropologists discern these subtleties through extensive field studies (ethnography) of indigenous peoples to understand the complex cultural and environmental circumstances that shape plant selection and use. They have observed that many medicinal species are used for other purposes as well, thus extending human exposure to pharmacologically active constituents.

Medicines overlap especially with foods, and some cultural groups, for example, the Hausa in Nigeria, acquire knowledge of some wild food plants through their experiences with those species as medicines (Etkin and Ross, 1994). In other circumstances the incorporation into cuisines of “novel” plants, such as unusually bitter, astringent, or otherwise unpalatable plants, takes advantage of the healthful effects of bioreactive species, some of which may later be used as medicine proper (Johns, 1994). The point is not to judge whether or not some indigenous group “got it right,” that is, used pharmacologically active plants in a way consistent with the principles of biomedicine, but to apply the techniques of bioscience as one aspect of comprehensive research based in extensive field study.

At the other end of the continuum are ethnopharmacologists whose primary objective is drug development. Logically this is the perspective of researchers who do want to know whether or not some indigenous group “got it

right" and if so how that lead can be pursued to discover new pharmaceuticals. Bioprospecting pharmacologists have begun to collaborate with botanists, who offer chemotaxonomic insights to guide the search for new sources of known drugs (on the principle that closely related plants have similar chemical profiles) and new plant compounds. For example, the potential to develop medicines for diabetes is suggested in plants that have insulin-stimulating effects, inhibit carbohydrate-digesting enzymes in the intestine, or increase glucose utilization (Raman and Skett, 1998). This research is primarily entrepreneurial (discovering products rather than indigenous knowledge) and necessarily involves only short-term field study with greater emphasis on laboratory and clinical phases. As such this version of ethnopharmacology is not as likely to uncover overlapping uses and the potential pharmacologic significance of certain indigenous food plants.

In the West the bioscientific perspective of ethnopharmacology is applied also to the study of foods. For example, researchers have found that the antioxidant lycopene, which gives tomatoes their red color, diminishes the risk of cardiovascular disease and cancers of the digestive tract and prostate (Rao and Agarwal, 1999). Similarly sulforaphane in broccoli has anticancer activity; hesperidin in grapefruit inhibits poliomyelitis, herpes, and influenza viruses; capsaicin in chili pepper lowers the risk of stomach cancer; sulfides in garlic and onion inhibit blood clotting; and glucaric acid in orange lowers serum cholesterol (Debrovner, 1993; Montanari et al., 1997).

These examples of healthful constituents in everyday (nonexotic) foods overlap the rapidly expanding public and scientific interest in complementary and alternative medicines (CAM), many of which are variably promoted as functional foods, medical foods, supplements, nutraceuticals, health foods, pharmafoods, phytofoods, and phytochemicals ("phyto-" denotes plant). Although the popularity of CAM has been primarily commercially driven, these products increasingly are subjected to scientific scrutiny. For example, studies suggest that constituents of saw palmetto protect against prostate cancers and that dandelion extracts are diuretic. Pharmacologic studies of previously uncharacterized medicinal foods also reveal potential risks. For example, the blood-thinning and insulin-promoting actions of ginseng may act synergistically with drugs prescribed for the same effects; Saint-John's-wort decreases the effectiveness of some pharmaceuticals, including Indinavir (used to treat HIV/AIDS); and licorice may increase the side effects of oral contraceptives (Newall et al., 1996).

Ethnopharmacologists of all persuasions want to move beyond catalogs of plant use and action to address issues of context. How are the activities of plant components affected by preparation according to real instructions for use? What is the outcome when foods, medicinal foods, medicines, and other biodynamic substances are combined? These are complex questions. They are also

the most interesting questions, and their answers will have the broadest implications for people who interact with biodynamic foods and medicines in their daily lives.

**ETIQUETTE AND EATING HABITS.** No society can survive or flourish unless its members accept rules governing food sharing and consumption. Mealtime manners, which govern the way food is eaten in the company of others, provide for giving and receiving small, vital, and constantly reiterated signs that these rules are in working order. Without them food would be hogged by the physically powerful, violence would frequently erupt during meals, civility in general would decline, and eventually society would break down altogether. Furthermore, the specific fashion in which a culture manages eating helps to express, identify, and dramatize that society's ideals and aesthetic style.

Civilized and considerate people the world over demand that meals shall be eaten with respect, not only for the food and the effort and good fortune it represents but also for the people in whose company it is eaten. Human beings normally eat in the company of others. The word "company" is derived from Latin, meaning "bread with," and therefore "those who share food." The act of sharing a meal becomes a symbol of every kind of relationship and of the acceptance of cultural values that may seem to have little to do with consuming nutrients. Since eating normally happens more than once a day, human beings turn meals into opportunities to learn and to practice "culture." Politeness at meals provides daily exercise in making socially desirable norms "second nature."

However, mealtime etiquette is not morality. It is convention, an agreement to behave, in the particular circumstances of mealtimes, as if one were virtuous. Like any convention it is liable to degenerate into a facade, which can be used as a barrier to protect power and class distinction.

### Taboo

Eating rules exist mainly to ensure that meals shall be shared peacefully, the reason being that such an outcome is far from inevitable. People have killed, chopped, and

Portrait of Emily Post, the American doyenne of good manners. PHOTO COURTESY OF THE LIBRARY OF CONGRESS.

submitted to fire what they are eating together; they are often armed with knives and certainly with teeth, primary human weapons. They are hungry, each looking out for his or her own interests, and they are sitting at close quarters. They might also be consuming alcohol, which lowers inhibitions. Mealtime rules provide not only the safety but also the predictability that allows eaters to relax.

Different societies have different ways of keeping violence out of the sacred eating space. In European and American cultures knives are on the table. Their blades are given rounded ends unless they are exceptionally competent "steak" knives. Rules insist on no pointing with knives, forks, or spoons. Diners should not impale their food on their knives to carry it to their mouths, or hold their knives in their fists (that is, too competently and therefore aggressively). They should direct their knives toward their plates with their forefingers, and they should lay down their knives with blades facing inward, not toward neighbors. Attempting to reduce the actual use of the knife, diners, when in doubt and if possible, use a fork or a spoon instead. North Americans traditionally cut their food then put aside their knives, blades facing in, and eat with their forks. Carving up a whole

joint or a bird in front of the assembled company would be, in many societies, an unthinkable barbarous act. The Chinese and Japanese, for example, have banned knives from the table altogether. They cut up everything in advance, far away and out of sight. The eating implements provided are blunt wooden sticks.

Mealtime manners usually work by keeping any thought of violence from occurring. Many myths, however, reveal the roots of the conventions by including a murder that is especially appalling because of its mealtime setting. The drama resides in the horror of that which good behavior while eating so successfully prevents. (An example is Homer's *Odyssey* 11: 409–420.) And because mealtime manners are a mild form of taboo, hearing about infractions, such as people flinging food about, wiping their mouths on the tablecloth, or grabbing food with their hands (especially where knives, forks, and spoons or chopsticks are the rule), causes shock or laughter.

During meals all mammals are extrasensitive to the possibility of enemies stealing their food or otherwise taking advantage of their concentration on eating. They are alert to tiny signs and abnormalities in the environment that otherwise they might let pass. For human beings, who normally eat in a previously prepared and protected area, this heightened attention is applied to the behavior of their eating companions. Strange table manners or an affront to a visitor's culturally formed expectations are often the subject of dramatic travelers' tales. Westerners, for example, might note with surprise and then find unforgettable the Arab custom of pouring tea into a glass until it overflows into the saucer beneath it. This is a sign in Arab cultures of magnanimity, but foreigners can misinterpret it as sloppy and incompetent behavior. On the continent of Europe, propriety enjoins diners to sit with both hands in full view of the company; most correctly, unused hands should rest on the table's edge, being visible only from the wrists. The Anglo-Saxon custom of permitting guests to sit with one hand hidden seems, to Continentals, at best a sad sign of naivete. Since mealtime etiquette is drummed into people so early and so thoroughly, its obedient practitioners rarely find it a matter for comment; they take it for granted. It is outsiders usually who report on the idiosyncrasies of a society's manners at meals.

### Consideration for the Company

Other themes expressed by systems of mealtime manners worldwide include who dines with whom and when, and the solidarity of the dining group; consideration for the needs, fears, and sensitivities of the other people present; and cleanliness, which may have as much to do with purity and all its connotations as with health. These themes may be articulated in mealtime rituals that are common to many cultures, or behavior may be highly idiosyncratic yet witness to widely held meanings. Mealtime rules simultaneously express preferences that are culture specific.

## VIOLENCE

To attack corn on the cob with as little ferocity as possible is perhaps the only direction to be given, since from the point of view of grace a series of ferociously snatching, teeth-bared bites that can be heard as well as seen, to say nothing of butter and corn fragments sprinkled on chin and cheeks, while delectable to the palate, is a horrible sight. (Post, 1937, p. 758)

The neighing sound that some people make when they laugh is ... unseemly. And the person who opens his mouth wide in a rictus, with wrinkled cheeks and exposed teeth, is also impolite.... If something so funny should occur that it produces uncontrolled laughter ... the face should be covered with a napkin or with the hand. (Erasmus, 1530)

## HOST AND GUEST

The diner who lets his *fan* (rice) bowl stay on the table and eats by picking up lumps of *fan* from the bowl is expressing disinterest [*sic*] in or dissatisfaction with the food. If he or she is a guest in someone's house, that is seen as an open insult to the host. (F. L. K. Hsü and V. Y. N. Hsü, "Modern China: North," in *Food in Chinese Culture*, edited by K. C. Chang, 1977, p. 305)

If you are fortunate enough, as a guest, to be given a piece of fruit by the ruler, you should suck the kernel clean and put it down the front of your robe, to show that you are not throwing any of his gift away. (*Li Chi*, compiled in the early first century B.C.E., translated by James Legge, 1967)

## NOISE AND TALKING

When eating refrain from speaking, lest the windpipe open before the gullet, and life be in danger. (Babylonian Talmud, c. 450 C.E.)

Certain hot foods are best when very hot. The technique for eating them is to draw in air over a narrow opening so as to hasten evaporation and diffuse the flavor. This is most effective when the air roughens the surface of the liquid. That is why hot soup, hot soup-noodles, hot congee etc. are best when sucked in with as loud a noise as possible. (Chao, 1956, p. 34)

[Do not mention at table] a rope in the house of a man who has been hanged. (Lord Chesterfield's letters to his son, no. 259, 1777)

For example, in modern Europe and America meals are eaten around a table, which expresses the oneness of the group. Solidarity established, the separateness and

## SNOBBERY

[Etiquette is] the barrier which society draws around itself, a shield against the intrusion of the impertinent, the improper, and the vulgar. (*Manners and Tone of Good Society; or, Solecisms to Be Avoided*, 1879)

Nothing indicates a well-bred man more than a proper mode of eating his dinner. A man may pass muster by *dressing well*, and may sustain himself tolerably in conversation; but if he is not perfectly “au fait,” *dinner* will betray him. (Agogos, *Hints on Etiquette and the Usages of Society*, 1834)

## DELICATESSE

Turn away when spitting to avoid spitting on or spraying someone. If any disgusting matter is spat onto the ground, it should ... be ground under foot lest it nauseate someone. (Erasmus, 1530)

Withdraw when you are going to vomit; vomiting is not shameful, but to have vomited through gluttony is disgusting. (Erasmus, 1530)

If you happen to have eaten something that cannot be swallowed, you should discreetly turn away and toss it somewhere. (Erasmus, 1530)

Drinking much and long leads to unavoidable consequences. Will it be credited that, in the corner of the very dining room, there is a certain convenient piece of furniture, to be used by anybody who wants it. The operation is performed very deliberately and undisguisedly, as a matter of course, and occasions no interruption of the conversation. (Louis Simond, *Journal of a Tour and Residence in Great Britain during the Years 1810 and 1811*, 1815, vol. 1, p. 49)

self-sufficiency of each individual is stressed. The cutlery is laid out like a fence surrounding every “place.” Everyone sits on his or her own upright chair. Portions are divided out before people begin eating and are served on separate dishes. Any crossing of the boundaries represented by the enclosed “place” is either a transgression (a “transgression,” derived from Latin, means a “stepping over”) or demonstrates great intimacy between people allowed to break this rule and transfer “tastes” from one plate to another. In this same culture it used to be thought polite and benevolent, therefore “good manners,” repeatedly to pass food to one’s companions. People are exhorted not to lean into someone else’s space; not to reach across the table, let alone across a neighbor’s plate; not to share the cutlery. Such insistence on the boundaries between the diners is different from the etiquette of people who eat from a common spread, taking from it with their hands, often sitting on the ground to do so.

## Equality, Hierarchy, and Reciprocity

When equality is the overriding theme of a meal, meat is likely to be prechopped or minced and perhaps formed into cakes of equal sizes, or all the ingredients might be mixed in one dish so everybody eats the same thing (Watson, 1988). But hierarchy frequently cuts across commensal equality. It matters, for example, who gets served first. Where a whole bird, representing the oneness of the group, is carved up before the diners, the proceeding ensures that differences are expressed. No portion is exactly like any other, and differing values might be assigned to each piece. Carving, in the Western tradition, was once called “doing the honors.”

The allocation of sitting spaces at a banquet is exceedingly important in many cultures and subject to specific rules. Often women, who usually have prepared the food, are not allowed to join the men in eating it. Written records of feasts in the European past frequently describe the seating of the guests while not bothering to say what it was they actually ate.

Hospitality, or accepting nonfamily members into one’s house, has always been thought a difficult or dangerous proceeding, and for this reason is often the subject of rules and constraints. Hosts have to make guests “feel at home,” yet guests must refrain from demanding different food, ordering the host’s children about, or otherwise overstepping their essentially passive role. Hosts are at home, giving, while guests are away, receiving, and these roles are underlined in different ways, for instance, in some of the rules for seating.

Meals eaten with friends and acquaintances are widely thought of as helping to bind a society’s members together, especially in cultures where familial solidarity is strong enough to create the potential isolation of people into family groups (Ortner, 1978). Such meals normally demand a repetition of the exercise at a later date, when the present guest will become the host. The imbalance created between hosts and guests demands to be righted and produces the highly desirable social virtue of peaceful reciprocity (Lévi-Strauss, 1969; Pitt-Rivers, 1977).

## Teaching Children to Behave

In all cultures children have to be taught mealtime manners, which deliberately complicate the actions of taking and eating. They learn gradually not to grab, splash, or shout at meals. They practice giving and receiving in the manner acceptable to the culture, and they find they must ask for rather than demand what they want. Children may also become familiar with social hierarchies or elaborate kinship patterns in their rule-bound expressions at meals, that is, how and when to keep quiet, how to hear and apply admonitions, how to wait and to share (Raum, 1940; Read, 1959; Richards, 1932, 1939). Mealtimes, with clear needs, swift rewards, and adult examples on view, are perfect occasions for children to learn to talk. It is understood that little children, if they are allowed to join the

commensal group, have not yet learned to “behave.” They may be permitted to run around, beg for tidbits from adults, and otherwise break the rules. Their eventual admission to adult status at meals is a kind of initiation and a proof that they now are capable of self-control.

### Noise

Different attitudes toward food are expressed by two types of mealtime manners as they relate to sound. For some groups the polite response to a meal is gratitude to the cook or the host for providing it and pleasure, which should be clearly dramatized. People are expected to express their delight verbally or to provide physical signs of it, like slurping their noodles and sighing with satisfaction. Contentedly burping after the meal may show a kindly abandon to the generosity of the host, who might be hurt if guests remain cool, detached, and apparently either unsatisfied or unimpressed by what has been offered them.

In other cultures people feel they should not be unduly interested in the food; they should at least appear to revel mainly in the company of the other people present. They refrain from exclaiming about the food, although a polite murmur of appreciation might be permitted. They must not look too enthusiastic for fear of seeming greedy. People are expected instead to concentrate on the conversation.

In some cultures talking during meals may be strictly undesirable. In others only certain people present are allowed to talk, or it may be deemed essential that everybody contribute to the conversation. The etiquette of eating from a common spread versus that of eating previously apportioned food interlocks with these preferences for either talking or keeping silent. The system in which each person eats from a separate plate divides the companions, and talk provides the needed interchange among them. People who take their food from a central dish or set of dishes necessarily interact in the process, so they concentrate on eating with fairness and consideration and tend to talk little. People who use chopsticks eat quickly because cut-up food, sizzling hot, could get cold if too much time is taken in chatting rather than eating. Talking for these last two groups tends to be done before the meal or afterward.

### Complication

Politeness, which overlays “nature,” is usually a complication of behavior deemed by other people to be “fitting” and “proper.” In the modern West, for example, where conversation is a necessary part of the formal proceedings at dinner, well-behaved people must nevertheless eat with their mouths closed. To eat and talk but never to be seen opening your mouth with food in it is far from simple. Dining “properly” and remaining relaxed while doing so (showing uneasiness at mealtimes is always distracting and annoying for the other diners) has to be learned and then honed by constant practice.

Silver punch strainer, London, England, 1757. According to proper eighteenth-century etiquette, punch was strained of fruit pulp as it was poured into cups. ROUGHWOOD COLLECTION. PHOTO CHEW & COMPANY.

Not being mannerly, and effortlessly mannerly, can arouse irritation, unease, disgust, contempt, and finally rejection by other people. Manners, which are supposed to ease relationships, can be turned into a series of tests to sift out people who have not learned the niceties and therefore are kept outside the privileged circles of the “well bred.” Here manners are no longer “for the sake of other people” but only for the complacency of some and the exclusion of others. Mealtime manners make a more draconian demand than most aspects of “proper” behavior because ignoring them can violate largely unexamined or unconscious taboos. People often use the differences between their own systems of manners and those of others to make derogatory judgments about those others. In the modern West people frequently shudder at or mock the behavior of their own ancestors, who, for example, ate with their hands.

Yet people who eat with their hands have just as many rules and elaborations as do the wielders of chopsticks or knives, forks, and spoons. People might, for example, always have to eat with their right hands (Needham, 1973) and might even have to restrict the number of fingers used on that hand. They must never reach for more food while still chewing and must never fill both cheeks or even fill one too full, which shows uncontrolled appetite. Hand washing is demanded before and after meals and sometimes during meals as well. No spilling or grabbing and no fiddling with the food is allowed, such actions being all too easy when eating with the hands. Eating gracefully, or the reverse, is defined, and rules establish how to take up a morsel and just how and how much to dip it into sauce. Restrictions govern general physical postures at meals, and the pressure is to offer delicacies to others. Rules such as these regulated eating

## CLOSING THE MOUTH

Item, that he fil not his mouth so ful of meat as he cannot hold his lips together while he is chawing: for otherwise, men shal look into his mouth, and see the meat rowle by and downe while he is eating: which is a foule sight and loathsome: and for that cause, a man must forbear to speake with meat in his mouth, except he have so litle as hee bee sure to hide it in his mouth while he is speaking. (*The Court of Civill Courtesie*, translated from the Italian, 1591)

## COMPLICATION

American manners [regarding the use of knife and fork] are, if anything, a more advanced form of civilized behavior than the European, because they are more complicated and further removed from the practical result, always a sign of refinement. (Martin, 1983, p. 124)

The expert removes the bones from his mouth with his chopsticks. (Chao, 1956)

behavior before the imposition of the set of cutlery now common in the West.

## The History of Table Manners

Mealtime etiquette is a conservative force in all societies. Since it expresses culture, it resists deconstruction and alteration. Manners do change over time. But no matter how trivial it may seem, any modification in a traditional mealtime convention is likely to be a sign of a momentous shift in socially determined sensibilities.

Forks have become in the West part of every diner's eating equipment. Eating with the hands is permissible only in a restricted number of cases, such as eating artichokes, asparagus, or radishes, or on informal occasions. The difficult, unnatural, skill-demanding fork has replaced fingers at nearly all tables most of the time. It took eight centuries to accomplish this.

Before forks achieved general usage as eating implements, people had to devise flat, hard surfaces on which each individual diner could impale portions with forks and cut them with knives. Those surfaces then had to be accepted and made available to everybody. The new plates ("plate," derived from the French, means "flat") were first metal, then ceramic, making them more affordable. They gradually replaced the traditional bowls and hollows carved into the dining table and the "trenchers" or bread bases for supporting morsels of food eaten with the hands. Even after the general acceptance

of the fork, polite people continued until the early twentieth century to feel free to carry their food to their mouths with their knives.

The provision of special implements for moving food from serving dish to plate also came about slowly. European manners gradually and unevenly changed from several people taking it in turns to dip the one shared spoon into the pot and to eat from it, to wiping the communal spoon carefully on a napkin before passing it on, to provision of a spoon for each person for dipping and eating, to wiping that individual spoon on a napkin after sipping from it before dipping it into the common dish again, to using a special spoon for serving and nothing else. A person must never forget and use his or her own spoon by mistake. All this purity required more and more cutlery.

The slow developments just outlined together with a growing restriction on bodily relaxation at table reflected an increasing desire for self-sufficiency and separateness in the culture. Ideally others should neither impinge nor need assistance. Such changes can be tracked in European and American history by studying surviving writings describing etiquette. These writings include pamphlets and lists of rules published from the medieval period down to the twenty-first century for people wanting to "polish" their manners, including their table manners, in order to become upwardly mobile. The sociologist Norbert Elias (1939) used these texts, especially those concerned with table manners, to show the development of Western inhibitions following the Renaissance, when Erasmus (1530) published the most accomplished and famous example and included in it a chapter on manners at meals.

The printing press helped disseminate books of etiquette, and learning mannerly behavior began to spread outside the narrow but innovative circles of the court first to the bourgeoisie, who became stricter than the nobility was about certain kinds of correct behavior, and then to everybody else. Elias chronicled not only the growth of separating "walls of restraint," underwritten by embarrassment, in Western culture but the gradual imposition of an insistence that people control and hide bodily functions, where once people were far more tolerant about such matters. In all cultures manners must have changed in analogous ways, even if the changes have not been recorded.

## Formality and Informality

Mealtime etiquette governs settings for meals, the seating of hosts and guests, dishes, decorations, lights, napkins and washing facilities, eating implements and their placement in the eating area, the sequence in which food is eaten, how food is served, the correct ways of issuing invitations to dinner, what people wear when eating, and much else besides. Each of these customs and artifacts has a specific meaning and a history. When all these things are enumerated, however, the reference is to full, formal meals, the ones with the widest range and intri-

cacy, where hospitality is offered to guests. Such meals are likely to be “feasts” on the occasion of events important for the community. People come together to eat when they wish to celebrate, especially when they are eager to express what is held in common (Douglas and Gross, 1981).

Feasts by definition are out of the ordinary, extravagant, complicated, often pointedly traditional, highly organized, and therefore commonly formal. The food itself is typically shaped or molded and prepared in elaborate, time-consuming ways, often requiring the efforts of many people. Preparing becomes part of the sharing. Ordinary eating is simpler, less copious, and takes less time; it is informal.

This does not mean that manners are less important at everyday family meals, but it does mean that decorum at these daily events is usually and deliberately lowered. Mealtime taboos are fiercely maintained (no one at a European or American meal puts his or her feet on the table, no one spits, or causes an uproar without disapproval), but formal flourishes are dispensed with. People might feel comfortable eating in silence, handle their food casually, or not clear the entire table before laying it for a meal. Membership in a high social class frequently entails relatively high decorum at ordinary meals. A deliberate lowering of decorum gives the strongest messages when the “full,” formal model is previously understood.

Formality by design increases social distance; informality brings people closer. In the modern Western world being “casual” has come to be seen as nearly always *de rigueur* because of modern egalitarian ideals and because modern society has more than enough devices for keeping people apart. The insistence that people shall behave casually but in the prescribed manner is in itself a mannerly social convention.

### Some Factors Informing Table Etiquette in Modern Europe and North America

Formality is a lot of work—work that has traditionally been performed with regard to meals mostly by women and by servants. In the course of the first half of the twentieth century, even upper-middle-class households learned to manage without live-in servants. The immediate result was the lowering of decorum, including that at the dinner table. Being served meals by people not part of the commensal group became part of the relatively unusual experience of dining in restaurants.

With the ongoing feminist revolution, women are no longer automatically expected to remain dedicated to the house and devoted to the maintenance of “polish.” Once again formality at the family dining table has diminished, even where once it ruled. However, one of the principles of manners has always been “Do not improperly impose upon others.” It is possible to accept a certain lowering of decorum at the dinner table as even more mannerly than formality once was. The rules of propri-

Comic valentine from circa 1930 spoofing the bad table manners of the newly rich. ROUGHWOOD COLLECTION.

ety are negotiated rules. Whatever is no longer thought proper is rude or at best ridiculous. Politeness at table as elsewhere has everything to do with the accepted conventions.

Formality is among other things the taking of time; elaboration takes time. In the “developed” world time has become part of the system of social constraints. People feel they have “no time.” The immediate effect upon manners of this culturally induced perception is almost invariably, again, to simplify them. Eating meals can become not a pleasure but something done purely out of necessity and as quickly as possible to get it out of the way in favor of other activities. Preparing food is often foregone entirely, and prepared food is substituted. Eating “fast food,” however, still conforms to the limits set by table manners. Predictability, equality, and cleanliness, all of them the concern of mealtime manners, are also assured by the fact that the food is always exactly the same, is served in similar surroundings, and is hedged about by a lot of paper wrappings and other signs that convey “cleanliness” and “control.”

Manners, including mealtime manners, are at present undergoing change and renegotiation in many human cultures worldwide; this is a sign of important transformations underway. Such modifications must take time and occur neither smoothly nor evenly. People increasingly come into contact with systems of manners different from their own. They often have to endure unpredictable and annoying behavior from others and relatively weak social mechanisms for preventing or punishing transgressions. Many complain that others have “no manners.” But as long as human society continues to function, manners will exist. And among the most fundamental of these are manners governing and involving eating.

**ETYMOLOGY OF FOOD.** The words of a language can be traced to two sources. Some have been a part of that same language as far back as its history is known, although, since no language remains fixed, they will have gradually changed in form and sound. Others are loanwords, borrowed from another language with which the speakers of the first have been in contact.

Food words fall into both categories. Food and drink are necessities of life, basic elements of which are likely to remain fixed (and to retain the same vocabulary) through the centuries. Yet innumerable details will

change (and demand new names) in response to taste, fashion, and the love of variety; also in response to the migration of peoples, the development of trade, and the transplanting of food species. Thus in English the names of foods and drinks mirror the cultural history of English speakers. Some names remain unexplained: no one knows the origin of “raspberry,” “syllabub,” or “toffee.”

Some basic foods have had the same name in English and in its ancestral languages all the way back to Proto-Indo-European, an unrecorded, reconstructed language that might have been spoken some time between 5000 and 3000 B.C.E. in the southern Russian steppes. Such words include *water* (compare modern Russian *voda* [water] and *vodka*), *mead* (Sanskrit *madhu* [honey]), *barley* (Latin *far* [emmer wheat]), *milk* (Latin *mulgere* [to milk an animal]). Also from Proto-Indo-European come the names of certain basic preparation methods, *bake* (compare Greek *phogein*), *brew*, and *broth* (Greek *broutos* [a kind of beer]).

The names of some foods go back to the unrecorded Proto-Germanic language of the first millennium B.C.E. (the immediate ancestor of English, German, and others) but cannot be traced to any earlier stage. This applies to *meat*, *bread* (German *Brot*), *honey*, *eel* (German *Aal*), *egg* (German *Ei*). Some of these words may have been borrowed into Proto-Germanic from other unrecorded prehistoric languages of Europe.

Moving forward in time, some Mediterranean foods and luxuries were introduced to northern Europe by the Romans. Thus English uses words of Latin origin for important products such as *cheese* (from Latin *caseus*) and *wine* (from Latin *vinum*) and also for a few fruits and vegetables that were first planted in northern Europe by the Romans, such as *plum* (from Latin *prunum*) and *fennel* (from Latin *feniculum*).

Certain new foods came to England with the Norman conquest in 1066. During the period of English-French bilingual culture that followed, English cuisine changed and developed rapidly. Thus many terms relevant to food were borrowed into English from Anglo-Norman, the dialect of Old French that was spoken in Medieval England. Examples include *pear* (French *poire*), *chestnut* (French *châtaigne*; originally from ancient Greek *kastanea*), *salmon* (French *saumon*), *sausage* (French *sau-cisse*). Anglo-Norman was also the source of names for cooking methods, *fry* (French *frire*) and *boil* (French *bouillir*).

English has continued to borrow food concepts from other cultures and food words from other languages. *Steak* comes from Old Norse, the language of the Vikings; *lozenge* from Arabic by way of Old French; *pickle* from Dutch; *tomato*, *chocolate*, and *chili* from Nahuatl, the language of the Aztecs. In modern times, with the globalization of tastes, this kind of borrowing has become even more frequent. So we have *curry* from Tamil or Kannada of southern India, *toddy* and *chutney* from Hindi, *pasta* and

*pizza* from Italian, *marzipan* from German (the word originated in Italian), *blini* from Russian, *tofu* from Japanese (the word originated in Chinese). Cooks and restaurateurs like to make the names of dishes evoke their origins by retaining an authentically foreign form, such as the French *coq au vin* and *tripes à la mode de Caen* (cockereel cooked in wine, tripe in the Caen fashion). They also like to use foreign names for methods of preparation, as in *chicken chasseur* (French *chasseur* [hunter]).

Local specialties in food and wine mean that place-names often have a special food meaning. *Cheddar* is a village in Somerset, England (but cheeses with this name are now made in many countries). *Cognac* and *Armagnac* are towns in southwestern France. *Parmesan* is an English form of the Italian adjective *Parmigiano*, meaning ‘from Parma’, a town in northern Italy. *Sherry* is an English form of the Spanish place-name *Jérez (de la Frontera)*; *Port* is an English form of the Portuguese place name *Porto*.

Since English is spoken so widely across the world, its vocabulary is astonishingly varied. Many foods have different names, and many food names have different meanings in Britain and the United States. *Cider* is apple juice in the United States; it is an alcoholic drink in Britain. *Corn* is maize in the United States, wheat in Britain. The spice called *turmeric* in Britain and the United States is known in South Africa as *borrie* (a loan from Malay by way of Afrikaans). The European spice known in Britain as *coriander* is called in Indian English *dhania* or *dhunia*; in the United States the fruit is called *coriander* but the leaves are called *cilantro*, a word borrowed from Spanish. The Afghan spice known as *hing* in Indian English is *asafoetida* in Britain and the United States, while it is *duivelsdrek* in South African English: this is a loanword from Afrikaans meaning literally ‘devil’s dung’ (because that is what asafoetida smells like). The spice called *jeera* in Indian English is *cumin* or *cummin* in British and U.S. English. Indian English *methi* is British English *fenugreek*. Indian English *sitaphul* is known elsewhere as *custard-apple*. Indian English *alu* is U.S. and British English *potato* (also British *spud*). The fruit *okra* (this name is borrowed from the Akan language of Ghana) is also known regionally as *gumbo* (borrowed from Mbundu of Angola), *bbindi* (borrowed from Marathi of India), and *ladies’ fingers*. The *chickpea* is also known as *chana* (borrowed from Hindi) and *garbanzo bean* (borrowed from Spanish). Even where the English names derive ultimately from a single foreign word, they may have different forms and connotations in different regions, like U.S. English *kabob* for British English *kebab* (a word that is Turkish in origin).

## Corn

The English words *corn* and *grain* are linguistic doublets: both of them originate in a Proto-Indo-European word (of about 4000 B.C.E.) that may be reconstructed as *gr̥nom*. This word meant ‘cereal grain’. As the Indo-European

languages grew apart, it took a different form in Proto-Germanic, in Latin, and in other early languages. In Proto-Germanic (about 500 B.C.E.) the form was *kurnam*: this became *korn* in Old High German and Old Norse and *corn* in Old English (Anglo-Saxon), and that is the immediate origin of the modern English word *corn*. In classical Latin, meanwhile, the form was *granum*. This became *grano* in Spanish and Italian and *grain* in French, meaning ‘cereal grain’, and the French word was borrowed into English. The French words *graine* (seed) and *grange* (barn) derive from the same Latin word.

What does *corn* mean? In British English it means ‘cereal’—and usually it means ‘wheat’, the favorite cereal of Europe. When English speakers in the New World (the “Indies”) encountered a cereal that was new to them, they invented a new name for it: *Indian corn*. In the United States, this name was eventually shortened to *corn*, which is why, in the United States, *corn* now means ‘Indian corn’. Meanwhile, back in Europe, where Indian corn was soon transplanted, people came to know it under the name *maize* (a Carib word, transmitted by way of Spanish *maíz*). In South Africa it has a different name again, *mealie* or *mielie* (a word borrowed from Afrikaans and said to derive originally from Portuguese *milho* [millet]).

So what are *Corn Flakes* made from? Indian corn, of course, because they were invented and named in the United States; but British people often assume that they are made from wheat, because that is what *corn* means in Britain.

## Sugar

Sugar, in ancient and medieval Europe, was a rare and costly spice. India was the nearest source of supply; sugar was shipped across the wide Indian Ocean, the Red Sea, and the Mediterranean to reach its European purchasers.

Sugar was originally traded as solid cakes. It was in India that granulated sugar was invented, perhaps about 200 B.C.E.; its ancient Indic (Pali and Prakrit) name, *sakkhara*, reflects this fact, because literally *sakkhara* (also *sakkara*) means ‘gravel, grit’. This word reached the ancient West along with the sacks of sugar; it was adopted into classical Greek (*sakkhar*, later *sakhar*), Latin (*saccharum*), and early Arabic (*sukkar*). Medieval Russians got their sugar from the Greeks of Byzantium, so they called it *sakhar*. Medieval western Europe bought sugar from Arab traders, and therefore gave it names that resemble the Arabic: medieval Latin *succarum*, Italian *zucchero*, Old French *sukere*, modern French *sucre*.

Sugar must have been almost unknown in Britain until Norman times. The English name for it is borrowed from Norman French: the form is *suker* or *zucker* in thirteenth-century manuscripts, then *suger*, and finally *sugar*.

## Cooking for William the Conqueror

The most familiar examples of food words borrowed into English from the Anglo-Norman form of French are

names for the meat of the pig, sheep, and ox, the three major farm animals of medieval Europe. In the Anglo-Saxon (Old English) language, just one basic word existed for each of these three animals, alive or dead. So also in Old French; so also in modern French, in which the basic words are *porc* (pig), *mouton* (sheep), and *boeuf* (ox).

In Norman times, English borrowed those three French words, *pork*, *mutton*, *beef*. So, unusually, ever since then, English has had six basic words in this semantic field, three for the living animals and three for the meats. Why were the extra three words borrowed at all? Why were the borrowed words used in the special sense of ready-to-eat meats?

The likely answer is that because the English nobles of that period spoke French and ordered their food in French, others eventually thought it fashionable and classy to use French for the names of fine foods. In just the same way, after a successful hunt, the huntsmen demanded in French to be served with *la veneson*, meaning literally ‘the game we just hunted’, and that is why *venison* has its modern English meaning of ‘deer meat’.

**EVOLUTION.** Jean-Louis Flandrin, in his introduction to *Food: A Culinary History*, sets out many of the crucial questions basic to our understanding of the evolution of human diet:

When and how did the eating behavior of human beings diverge from that of other animal species? Did humans distinguish themselves by the type of variety of foods they ate? By the fact that they prepared their food before eating it? By the ceremonial forms with which they surrounded the act of eating? Or by the conviviality of dining and its characteristic social forms? (p. 14)

These questions, as they relate to the evolution of human foodways, remain unanswerable. A major reason is the vast gulf that separates the living from earlier ancestors. Today, virtually all humans subsist on the products of agricultural activities, which include the raising of domestic animals for food. However, this way of life developed very late in the course of human evolution, with the domestication of plants appearing in several locations around the world at some point after 12,000 years ago; the domestication of food animals followed somewhat later. The vast earlier time, during which humans evolved from more primitive beings, was marked by other forms of subsistence. This time span, more than six million years in duration, witnessed dramatic changes in human biology, behavior, and adaptation. Although we have a treasure trove of fossil bones and archaeological materials that document much of this development, there is little in the record that can inform us of the precise dietary items consumed by these remote ancestors of ours, or enable us to answer the questions posed by Flandrin. There are, however, tantalizing hints of the ways of life followed by these earliest members of the human family, and in this essay, this record will be described, and the available evidence for the evolution of human foodways evaluated.

The data at our disposal for this investigation include the fossil bones and teeth of our ancestors, testaments to their evolving biological structures. There are also the residues of their activities, in the very earliest deposits often preserved as parts of natural accumulations of organic and inorganic remains, jumbled in with the fossil bones of very early human ancestors. Later in time, we find the archaeological remains of the actual living areas, where our ancestors slept, made tools, prepared and ate their food, and often buried or left their dead. All this varied information provides important insights about our evolutionary past, but it is very incomplete data for reconstructing dietary patterns. For example, very little in the way of actual food remains is found during archaeological excavations, and only relatively durable items like animal bones are preserved. This may provide some indication of the presence of meat in the diet, but it is not clear just how much it represents the total subsistence pattern and how much was composed of other foods, like vegetables and insects, which leave no archaeological traces. Similarly, the bones and teeth of our ancestors may preserve chemical and other traces of the sorts of foods that were emphasized in their diets, but these signs are often complex and must be carefully evaluated.

Given the difficulties in deciphering the actual residues, other, more indirect, sources of information have come to play an important role in reconstructing the foodways of our ancestors. These data come from the study of our closest living primate relatives, the chimpanzees, and observations recorded from the anthropological studies of those few modern human groups, called gatherers and hunters, who did not practice agriculture, but subsisted on an assortment of gathered vegetable foods, the collection of small animals, such as insects and small vertebrates, and the occasional successful hunting of larger animals. Comparisons with these living examples are often used to furnish clues to what sorts of foods our ancestors consumed. However, correlations of this sort have numerous limitations, and they must be used with caution. Chimpanzees and humans have had separate evolutionary pathways for at least six million years, and it is possible that during this time, chimpanzees have changed as much as humans in their biology and adaptation, making comparisons of living chimpanzees with our earliest ancestors tenuous at best (we have no fossil record of the specific evolutionary history of chimpanzees). Further, those few living gatherers and hunters who have been studied exist in environments that may be dramatically different from the locales of our ancestors. Finally, and perhaps most importantly, our early ancestors were neither bipedal apes nor humans in fur suits, but a series of biologically and behaviorally unique species whose way of life and biology are now wholly extinct.

Both modern chimpanzees and those gatherers and hunters who have been studied, and do not live in very specialized environments (like the Arctic, for example), have somewhat similar diets. The field research by Jane Goodall and her associates on chimpanzees living in the Gombe National Park in western Tanzania, as well as observations from other chimpanzee living-sites in Africa, indicate that these animals are overwhelmingly vegetarians, with a broadly based diet composed, at the Gombe, of the fruits, leaves, stems, blossoms, and gums of more than eighty different plants. Chimpanzees, however, emphasize a variety of fruits as the major part of their diet. Chimpanzees have also been observed consuming insects, sometimes using twigs, specially broken off and trimmed as tools, to obtain termites. Chimpanzees (often males), behaving together in a cooperative fashion, also deliberately hunt, kill, and eat a variety of small vertebrates, including bush pigs, monkeys, and antelopes. Meat, however, makes up a very small percentage of their total diet.

Human gatherers and hunters in tropical or subtropical areas also subsist on a diet that emphasizes a broad array of vegetable food sources, with smaller amounts of insects and vertebrate animals. The exact percentage of each of these elements differs seasonally or yearly, as well as varying between specific groups.

Like living gatherers and hunters, until the advent of agriculture, our ancestors probably lived an unsettled

existence, regularly shifting their encampments to new locales in search of resources. Food storage would have been very difficult, and consumption of collected and hunted foods was probably immediate. Groups would have been small, with the social organization flexible enough to allow group size to fluctuate with the seasonal availability of food and other resources.

These comparisons provide only a very limited insight, and for more information, it is necessary to examine the direct evidence from the archaeological and fossil records.

### Diet and Human Evolution

A variety of comparative genetic studies document that chimpanzees are our closest living relative. It has been estimated, for example, that humans and chimpanzees share about 98.5 percent of their genetic material. Calculations of the rate of genetic change over time indicate that humans last shared a common ancestor with this African ape between five and eight million years ago. This is the period when the evolutionary line that eventually led to living humans split from the line that led to chimpanzees, representing the beginnings of human evolution. The living and extinct members of this human evolutionary lineage are traditionally grouped into a biological family, the Hominidae, members of which are known as hominids.

We have no fossil or other evidence of the earliest members of the hominid family, just after they split off from the lineage leading to chimpanzees. We do not know what sorts of environments they lived in or what sorts of foods they ate. Because chimpanzees are native to Africa, and the earliest known hominid fossils are limited to Africa, it seems reasonable to place the homeland of the human family on that continent.

### The Earliest Hominids

The recognition of Africa as the human homeland first came in 1924, with the discovery of the fossilized skull and jaw of a young child at T'aung, in the Cape Province of South Africa. Named *Australopithecus africanus* by its discoverer, Raymond Dart, hundreds of additional fossil specimens of this group, known collectively as the australopithecines, have subsequently been uncovered in south, east, and central Africa. There are now at least eight species of australopithecines, sometimes placed in other genera, like *Paranthropus* or *Kenyanthropus*. The australopithecines lived in Africa from about four million to perhaps as late as one million years ago. Like all members of the hominid family, they walked upright, allowing them to efficiently carry objects and food. Chimpanzees habitually walk on all four legs. However, the australopithecines were apelike in many of their biological features, possessing small, chimpanzee-sized brains in an apelike skull with a large, projecting face positioned out in front of the braincase. Their teeth were humanlike in form, but they possessed massive back chewing teeth, the premolars and molars, that were much larger

than those of living humans. The australopithecines, like all hominids, possessed nonprojecting canine teeth. This is in marked contrast to the large, tusklike canines of the apes. Like gorillas, australopithecines also seem to have been sexually dimorphic in body size, with the males considerably larger than the females.

There are fossil bones found in East Africa of still earlier-in-time creatures, for example, *Orrorin tugenensis*, at six million years, possibly the earliest hominid yet discovered, and *Ardipithecus ramidus*, who lived about four and a half million years ago, but little is currently known about these creatures and their biology.

The fossil bones of the australopithecines are most often discovered in natural accumulations that are the result of various sorts of geological activities. These fossil bones may have been transported by water over long distances before they were deposited in their final location. They are only infrequently discovered in a context that represents the locale where they actually lived. Thus, little is known about the kinds of environments in which the australopithecines lived, or how the various australopithecine species may have differed in habitat usage or in food choice and general diet.

For many years after the initial discoveries of the australopithecines, there was a prevalent idea that these creatures lived on the open grasslands or savannas of eastern Africa. According to this theory, their habitat would have provided only a limited selection of foods, and was the selective factor responsible for the development of hunting and meat eating. More recent reconstructions, however, have revealed a much more complex environmental context for these early hominids, with evidence for the use of forests and woodlands. Just how important hunting and meat eating has been in human evolution continues to be debated, and its importance in the ultimate appearance of modern humans remains unclear.

Australopithecine fossil bones have been carefully examined in a number of ingenious ways, in order to learn more about their dietary patterns, but thus far with only limited success.

For example, on the basis of comparisons with the teeth of other mammals, it is clear that these early hominids were not specifically adapted to meat eating. As in modern humans, the chewing surfaces of the teeth are covered with thick layers of enamel. Some australopithecine species, known as the "robust" australopithecines, possessed truly massive back teeth, along with very large jawbones to house them, and large chewing muscles, sometimes so large that they formed a crest on the top of the skull. These general biological features of australopithecine jaws and teeth suggest that they emphasized the chewing of coarse vegetable food sources, but not the consumption of grasses, whose high cellulose content would have been very difficult for these creatures to digest.

Other studies of the dentition have attempted to determine more specific aspects of the dietary patterns of the australopithecines. One series of studies utilized scanning electron microscopy to examine the minute scratches and pits left by food particles on the chewing surface of the teeth. The results of these observations suggest that some of the australopithecines ate a diet rich in fruits, while others were consuming a more varied, but basically vegetarian, diet. One problem with these sorts of studies is that they tend to focus on the final meals the creatures ate before they died, providing a somewhat limited view of their overall diet, especially if they were seasonally exploiting a variety of different habitats and foods.

Other studies have examined the chemical composition of australopithecine fossil bones. One study employed the ratio of calcium and strontium in the fossil bones to determine whether the australopithecines were generally herbivorous, carnivorous, or omnivorous.

Another chemical analysis, based on staple isotopes including  $^{13}\text{C}$  and  $^{12}\text{C}$ , has reached a conclusion similar to that from the calcium-strontium analyses: some australopithecines, at least, were consuming animal foods, though the identity of these animals, and whether they were vertebrates or invertebrates, has not been determined.

These studies continue to support a variety of opinions about the dietary patterns of these early hominids, with some anthropologists suggesting a diet based primarily on fleshy fruits, nuts, and seeds, while others advocate a more broadly based diet, including some animal foods.

There is no direct evidence that the australopithecines collected foods to be brought back to some central camp to be consumed as part of a group activity. Rather, like chimpanzees, it appears likely that they consumed food continuously as they foraged in their environment.

### The Evolution of the Genus *Homo*

Good evidence of the evolution of members of our genus, *Homo*, begins to appear around two million years ago at sites in East Africa. There was a dramatic increase in brain size, from the 500 ml common in the australopithecines to brains as large as 800 ml in these early humans (though still about half the size of those of living people). They also possessed smaller back chewing teeth. Chipped stone tools, first used about two-and-a-half million years ago, now became more common. These durable tools, made from water-rounded pebbles, are known as Oldowan tools. They were made by striking two stones together, knocking off chips to produce a cutting edge or point. Though crudely made, their development represented a major advance in the ability of the early hominids to exploit a wider variety of food sources. Hominids lacked sharp and hardened claws, as well as projecting and pointed canine piercing teeth, making them inefficient in dealing with many potential food sources. For example,

without a digging tool or claws, many subterranean foods like insects, small burrowing mammals, tubers, and rhizomes, would have been impossible to obtain. The australopithecines are only rarely found in association with these chipped pebble tools, and most anthropologists believe the first stone tool makers were early members of the human genus *Homo*.

Also found at this time are animal bones, mainly from antelopes, with butchery marks made by a sharp stone edge. Although isotopic studies have indicated that the earlier australopithecines may have consumed animal foods, these cut marks represent definitive evidence of early meat eating. What is still being debated is the origin of these bones. They may have been the result of hunting activities, which is entirely reasonable given our knowledge of the cooperative hunting patterns of chimpanzees, but some scientists have suggested that they may also have been the result of scavenging activities. A safe way, it is said, to obtain bones with scraps of meat still adhering to them would be to claim animal bones from a predator kill after primary scavengers, such as hyenas and jackals, have finished with them. Thus, the initial meat eating in human evolution, according to this view, was to utilize stone tools to scrape off bits of rotting tissue from the bones of predator kills. One major flaw with this notion is that no primate is equipped with digestive mechanisms to protect them from the serious consequences of eating spoiled meat.

By about 1.8 million years ago, there are a number of different species of early *Homo* coexisting in eastern Africa. In addition, several species of robust australopithecines were also living at this time. What the possible dietary differences, if any, between all these hominids is unknown.

### Expansion Out of Africa

At some point after 1.8 million years ago, in one of the most momentous events in human evolution, the hominids begin to move out of Africa. One site along the Jordan River Valley in Israel, dated at about one and a half million years old, is located along what must have been a major route into Eurasia. Along with stone tools similar to those from Africa were found numerous bones of African mammals, suggesting that the hominids were not the only creatures moving out of that continent.

Hominid sites in the Republic of Georgia and on the island of Java also testify to this dramatic increase in range. Although the reasons the hominids left Africa at this moment are unclear, one reasonable explanation is that stone tools enabled hominids to expand the range of dietary items open for exploitation, allowing them to move into new habitats.

During the course of the next million years, hominid brain size increased, so that by about 300,000 to 400,000 years ago, the volume of the braincase reached 1,200 ml,

within the range of living humans. It may be that there was an associated increase in body size during this period as well. Increasing brain size would have required greater intakes of oxygen, as well as nutrients. It has been suggested that this brain size expansion relied on increased amounts of dietary fats. Hunted animals could have supplied these fats, but gathered insects, many of which are richly endowed with this nutrient (especially the essential fatty acid, linoleic acid), are equally likely sources. Larger body size also necessitated a greater number of calories.

The occupation of the European subcontinent appears to have taken place later than human expansion into more hospitable habitats in Asia. This is no doubt related to the presence of glaciers, which, beginning about two million years ago, periodically covered major parts of Europe. The earliest occupation site in Europe, dating to about 800,000 years ago, is located in northern Spain, near the present city of Burgos. From that time onwards, hominid presence in Europe was closely tied to the advance and retreat of the glaciers, with the continent relatively uninhabited during times of maximal glacial activity.

By 500,000 years ago, hominids, placed in the category *Homo erectus*, were intermittently occupying a large cave on the outskirts of what is now the village of Zhoukoudian, about twenty-five miles from Beijing, in northern China. Although there was no glacial activity in this part of Asia, winter would have been severe (Zhoukoudian is about as far north as Philadelphia). While it remains unclear if hominids actually wintered this far north, the earliest well-documented evidence of fire has been found here. Fire allowed hominids to use food sources that would be uneatable, or actually toxic, without cooking. Burned deer bones, as well as those with cut marks, testify to the use of meat by the inhabitants of the cave, but whether the meat was obtained by hunting or scavenging remains unknown.

From about the same time, a hominid skull was found in Ethiopia with cut marks on its frontal bone, suggesting skinning or scalping. Cannibalism has been documented at a number of other, later-in-time hominid sites; was the flesh a part of the diet, or was eating a dead friend or relative part of a ritual?

### Modern Human Origins

The last 200,000 years of human evolution are much richer in data because actual living places have been located and excavated. Prior to this time, only a very few sites, like Zhoukoudian, represented the remains of an encampment, where the evidence of hominid activities are directly preserved. By about 115,000 years ago, our ancestors had begun the practice of the deliberate burial of their dead, thereby reducing the risk that the body would be destroyed by scavengers. Burying the dead re-

sulted in a vast increase of ancient skeletons that have been preserved for study.

There continues to be debate about the precise way by which living humans emerged from our earlier ancestry. Some anthropologists suggest that modern humans evolved from these earlier hominids and, thus, are the culmination of a very long evolutionary history in various geographic areas. For example, living Asians are the descendants of ancestors who reached Asia more than a million years ago.

Most anthropologists support another theory, that all modern humans originated in Africa some 100,000 to 300,000 years ago and, subsequently, spread out from there to populate the rest of the planet, replacing the earlier hominids who were already living in these areas, descendants of the much earlier initial expansion.

One extinct fossil group that has figured prominently in these theories is the Neanderthals, a group of hominids who lived in Europe and the Middle East from about 130,000 to about 30,000 years ago, when they disappeared from the scene. Because they lived in Europe, where the most intensive archaeological investigations have taken place over the last 150 years, we have much more evidence about these creatures than about any other fossil hominids. This has provided a rich data source, but it also has a number of serious limitations. The most important is that emphasizing the Neanderthals gives a very Eurocentric view of human origins. The final glaciation occurred during much of the time Neanderthals were in Europe; this made major portions of the continent uninhabitable. Those parts that could be occupied by humans represented marginal environments that would have limited population density to extremely low levels.

Given the harsh environments of Europe in which the Neanderthals were living, vegetable foods were probably relatively scarce through much of the year, and meat was almost certainly a major dietary resource. This is confirmed by chemical analyses of their bones, which indicate that for some Neanderthals, fully 80 percent of their diet came from meat. The bones of numerous large animals, such as deer, aurochs, wild boar, and horses are preserved at Neanderthal sites, along with smaller animals. At sites along the Mediterranean, shells testify to the consumption of seafoods. Our evidence for the diet of peoples contemporary with the Neanderthals, but living in Africa and southern Asia, remains limited. At one site, located on the very southern coast of Africa, Klasies River Mouth Cave, there is abundant evidence of the use of a variety of food resources, including land and sea animals and shellfish. Because much of our current evidence comes from humans, like the Neanderthals, who lived in a harsh environment, the emphasis on hunting and meat eating that has come to characterize the diets of earlier hominids may represent a very biased picture.

Although the precise evolutionary relationships of the Neanderthals to living humans remain shadowy, ex-

cavation of their sites has revealed a complex picture. Often, living areas with hearths and signs of social areas around them have been uncovered. The bones of selected parts of animals, often with butchery marks on them, are scattered about. Clearly, Neanderthals, like living human gatherers and hunters, were carrying back to a central camp chosen pieces of animals. They may also have brought back other dietary items from their foraging and hunting activities, but the relative absence of small animal bones suggests that they may have been consumed immediately where they were found. It is quite possible that they sat around a fire sharing and consuming food, perhaps engaging in the uniquely human dinnertime interactions of storytelling and discussions of the day's activities. It is unclear, however, if the Neanderthals were actually able to use language, so this reconstruction remains a tentative one.

Sometime after 40,000 years ago, modern human-like peoples appeared in Europe, perhaps migrating there from their origins in Africa, or developing from ancestors already living in Europe. These modern humans brought with them new sorts of tool-making technologies, based on a broader array of raw materials, such as ivory, bone, and wood, with a wider assortment of beautifully made stone tools that show far greater sophistication than those made by the Neanderthals. The first artistic expressions also made their appearance at this time, with plastic art in the form of ivory and bone carvings of animals and people. Deep inside caves, they produced engravings and painted images of animals, and occasionally humans, some of them of great genius.

The sites occupied by these modern humans are littered with the bones of the same sort of animals, the earlier Neanderthals hunted, but the concentrations of bones indicate greater skills in hunting and a corresponding larger number of captured animals. This is also the case with much larger accumulations of shellfish along the coast.

These early modern humans continued this sort of hunting activity to the end of the last glacial period, about 12,000 years ago. In Europe, the retreat of the glaciers resulted in the spread of forests and a major change in dietary habits, with peoples hunting forest animals, like deer and rabbit, and utilizing to a much greater extent the riches of the sea. By this time, however, peoples in the Middle East and along the Yangtze River Valley in southern China were beginning to experiment with the cultivation of plants, which represented the beginnings of the agricultural revolution, and formed the foundations of settled urban life and the origins of civilization.

Although this sketch brings together much of our current knowledge of the evolution of human foodways, much clearly remains to be learned. For one thing, it tells us little about how human diet changed from eating what was necessary for nutritional needs to consuming what was enjoyable and pleasant to eat. Perhaps our ancestors always selected those foods that were enjoyable to eat,

bringing about the basis of the consumption of food as a central focus in the social life of humans.

**EXTENSION SERVICES.** Extension services extend information to users—farmers, growers, and homeowners. The Cooperative Extension Service (CES) is a publicly funded research and education network linking the resources of federal (U.S. Department of Agriculture), state (land-grant universities), and local (county) governments. The common mission—helping people to solve the problems that affect residents in U.S. communities—remains unchanged since its beginnings in the late 1800s.

Early in our government's development, George Washington and Thomas Jefferson advocated a national agency for teaching the agricultural sciences. Many years later, CES evolved from the needs of rural people for local education in agriculture, business, and home economics. In the 1800s, farmers needed help solving problems such as controlling insects or soil erosion or applying

the right amount of manure to crops. Nonfarmers needed an education in business and trade. Housewives needed information on family nutrition and food preservation. In response, the Morrill Act of 1862 provided for the establishment of at least one college in each state. Under this act, many states established colleges of agriculture whose objective was to teach agriculture and the mechanical arts without excluding the classical studies.

In 1887, the Hatch Act established an agricultural experiment station at each land-grant college as well as a system of cooperative funding between the USDA and land-grant institutions. As a result, scientists and educators at experiment stations conducted research, published the results, and disseminated information to farmers. Several years later, in 1890, the second Morrill Act extended the land-grant provisions to the sixteen southern states and ultimately led to the establishment of land-grant universities for black students.

Seaman A. Knapp (1833–1911), a former professor of agriculture in Iowa, is credited with starting the agricultural demonstration method around the turn of the century. He conducted farm demonstration work in Louisiana and then served in the Department of Agriculture as a special agent to promote better methods of farming in the South. His work led to the development of the Farmers Cooperative Demonstration Work division, which he headed. The demonstration method proved effective and was copied by CES personnel throughout the country; it remains an important CES tool today.

The Smith-Lever Act of 1914 established the CES as we know it today—a partnership among federal, state, and local governments. Land-grant colleges and the USDA were directed “to work together to provide for the practical and liberal higher education of all Americans,” reaching out to teach agriculture and home economics both in and outside of colleges. In 1925, the Purnell Act added agricultural economics, rural sociology, and home economics to the experiment stations’ mission. The Extension Indian Reservation Program (EIRP) was authorized by the 1990 Farm Bill, and provided for the establishment of extension education programs on Indian reservations and in tribal jurisdictions.

Some states were early in recognizing the need for agricultural education. In 1857, the Agricultural College of the State of Michigan was founded. The Michigan Agricultural Experiment Station at Michigan State University, founded in 1888, was among the first stations cre-

ated. The first county agricultural agent in New York State was hired in 1911 with funds provided by a Chamber of Commerce, a railroad, and the U.S. Department of Agriculture. New York was one of several states that went one step further, and by state legislation, created a partnership between the State Extension Service and the state itself. Alaska established its first experiment station in 1900.

The Cooperative Extension Service has kept pace with the farmer’s search for ways to remain economically and environmentally viable. The Sustainable Agriculture Research and Education (SARE) program works to increase knowledge about—and help farmers and ranchers adopt—sustainable agriculture. To advance such knowledge nationwide, SARE administers competitive grants for research, education, and professional development. In other areas, CES offers programs to help children and their families cope with disasters and develop an emergency preparedness plan.

To contact a Cooperative Extension Service locally, check the government listing in your telephone directory for Cooperative Extension Service, or look under “Agriculture.” Information about national programs can be obtained from the following address:

**FADS IN FOOD.** Food fads are interwoven with people's lifestyles, trends, and class aspirations. In all forms, fads are usually ideas that enjoy a quick popularity and soon disappear. Some fads, however, may actually become trends that develop into accepted style, indicating where society is moving. Fads in food are not a new occurrence. Ancient Roman recipes document demand for fattened snails and dormice as popular appetizers. During the 1700s, Americans craved ice cream, newly introduced from France, and lobster Newburg became fashionable in the 1800s. Lollipops were the rage in the 1920s. Current nostalgia for "retro" 1960s foods, such as fondue, accompanies a renewed interest in retrospective house and automotive design.

### Health Food Surges in Popularity

Nutrition is often a rationale for food fads. In the late 1800s, Kellogg, General Mills, and other manufacturers created cereals from grains, in the interest of promoting a cleansing diet. Turning fad into substance, the interest in health food became entrenched in American diets over the succeeding decades, with foods like smoothies, meatless burgers, and whole wheat baked goods emerging in the marketplace. Fears of irradiated foods, the drive for organic, calorie-reduced foods, brand name diets, and multivitamins all contributed to the faddish style of healthy living. Vegan and macrobiotic diets, brown rice, tofu, and "live foods," now readily available, once were fads. Vegetarianism, seen as a fringe diet, has become mainstream, and organic ingredients are now basic supermarket fare.

### The Orient and Other Ethnic Influences

America's fascination with the "exotic Orient" is an example of the pervasive influence of ethnic food fads. In the 1930s Chinese mah-jongg parties were popular among the socially style conscious. Accompanying food included *egg foo yung* and fried rice. Oriental themes characterized popular restaurants like Trader Vics, where diners could surround themselves with a sanitized Western version of exotic travel. Bars served unusually named Polynesian drinks with paper parasols. A Hawaiian craze followed, and backyard luau parties paralleled the emergence of Polynesian restaurants. Processed Spam with a

sweet and sour sauce was a popular dish. Rumaki, a chicken liver, bacon, and water chestnut hors d'oeuvre, wowed guests. Japanese steak houses cooked sukiyaki and tempura before admiring diners.

Many other ethnic groups have contributed to fads in American cuisine. In the late 1960s the growth of the civil rights and Black Power movements led to the rediscovery of African-American roots, including southern soul food. Grits, collard greens, and ham hocks were served side by side with other American traditional foods. Interest grew in Zen Buddhism, Hinduism, transcendental meditation, and other beliefs of India and Asia, which emphasized the spiritual aspect of foods. The immigration of Latinos, Vietnamese, and Middle Easterners have added to foreign food interests. Immigrant grocers have introduced new foods to Americans, increasing demand for exotic imports. In the late twentieth century, fusion cooking, combining several cultural food styles, created a second wave of interest in Oriental "style" foods, popularizing sushi bars and sushi kits.

### Travel and Tourism Contribute

Since the 1880s, immigrants and overseas tourism have influenced American cuisine. While some believe that GIs returning from World War II initiated the discovery of foreign food in postwar America, there is no strong substantive evidence to this effect. Sociologists theorize instead that, with an improved lifestyle, Americans had time and resources for travels abroad, from which they brought home cookware and ingredients. Hibachis enabled the suburbanite to barbecue Japanese style; fondue pots evoked trips to Zurich; copper pots decorated the French gourmet kitchen. Italian pizzerias and spaghetti houses sprang up to meet the demand for Neapolitan food. Chains of Italian restaurants and take-out pizza counters are their descendants.

Similarly, the popularity of Scandinavian design in the 1950s included appreciation of the smorgasbord, deli plates, and unusual drinks, such as Aquavit. European simplicity was not inexpensive. Stores featuring the high-end styling of Dansk, Braun, and later Crate and Barrel kitchenware changed the appearance of home kitchens and tables.

## Haute Cuisine

Fashionable in the last century, haute cuisine restaurants featured haughty waiters and showy decor. Servers cooked flambéed dishes, such as crêpes suzette, tableside. At home, any recipe that evoked the Parisian food scene had style. Chiffon pies with meringue toppings suggested restaurant desserts. In her kitchen, the trendsetting housewife would use readily available preprocessed sauces for dishes, such as lobster Thermidor, beef stroganoff, and chicken divan, served in chafing dishes to recreate the fine dining of four-star restaurants.

## Media Influence

Food magazines, epitomized after 1941 by *Gourmet* magazine, promoted food as fashion. *Sunset* magazine depicted the Western California scene, a sophisticated style of casual living, including football weekend tailgating, backyard cocktail parties, and barbecues. *Playboy* appealed to the urban bon vivant with a monthly column for the male chef, contributing to the craze for shish kebabs.

**The chef as personality.** The cult of personality chefs created through television programming resulted in the notion of the chef as star and creator of fancy cookbooks based on image, as well as in the exploding growth of fancy foods. One of the most significant personalities was *The French Chef*, Julia Child. She led the way for other television personality chefs to teach home viewers about good cuisine. James Beard, a food writer and chef, popularized classic American cooking. Paul Prudhomme, a Cajun New Orleans chef, demonstrated the “blackened fish” style of cooking. He used fiery spice rubs on fish, then seared them over high heat. There were many other food celebrities in the 1960s. In the 1990s, television’s Food Network catapulted interest in the celebrity chef, professional techniques, and personalized ingredients. The growth in cooking stores and vocational cooking schools is a direct response to the cult of the personality chef. Through these chefs, recipes that made use of goat cheese, aioli, beurre blanc, and green peppercorns became trendy pantry staples.

Among the fads connected to food are political movements targeting agricultural practices. In the 1960s César Chávez led a boycott of grape harvests in California to advertise the plight of farmworkers. Bans on large tuna nets in order to save dolphins were an early precursor to contemporary concerns about overfishing.

## Time Savers

As early as the 1900s, the goal of saving time created fashionable food fads. Refrigerators allowed homemakers to create quick, chilled desserts, epitomized by heavily sweetened marshmallow salads, fruit cocktails, and gelatin parfaits. The crock-pot, blender, and electric wok all promised to save time. One notable example that has faded is the 1980s “Impossible Bisquick Pie,” in which preblended ingredients sink to the bottom of an egg custard to form the “crust.”

## Space-Age Influence

Fascination with the National Aeronautics and Space Administration (NASA) and the space race in the 1960s produced many fads. Even before the emergence of health foods and healthy planet foods, space technology influenced trends, especially snacks. TV dinners and other aluminum-clad, quickly prepared foods surged in popularity. After the astronauts appeared on American television, anything freeze-dried or dehydrated, previously associated only with military rations or camping, became food for the modern age. Space sticks, chewy rolls of power food flavored with vanilla or chocolate, predated today’s energy bars. Tang, the sugar-powdered orange drink, was advertised as “drunk by astronauts.”

A fad develops as a result of a social aim, interest in other cultures, and advances in technology that promise that the home cook can become a chef like Escoffier—or at least cook like a pro. Some, like space sticks, fade with time, while others, such as organic foods, have helped to change dietary and farming practices. Within an evolving lifestyle, food fads both reflect and change contemporary society.

## FAO (FOOD AND AGRICULTURE ORGANIZATION OF THE UNITED NATIONS).

The Food and Agriculture Organization of the United Nations traces its origin to the foundation of the International Agriculture Institute in 1905 under the pioneering work of David Lubin. This institute, which preceded FAO, consisted of forty member nations and sponsored the first World Agriculture Census in 1930, a census which has been undertaken every ten years since that time and which has become one of the responsibilities of FAO since 1950.

The Food and Agriculture Organization was born out of the Hot Springs Conference held by forty-four nations at the Homestead Hotel, Hot Springs, Virginia, in May and June of 1943. It was established as an agency of the United Nations on 16 October 1945 to assume the work of the International Agriculture Institute and is

presently governed by the U.N. Conference of Member Nations. The Conference convenes every two years to review the work carried out by the organization and to approve its programs and budget for the next biennium. The director-general of FAO serves a six-year term. In addition to its headquarters in Rome, FAO maintains five regional offices (Africa, Latin America, Asia and the Pacific, the Near East, and Europe), five sub-regional offices, five liaison offices, and over seventy-eight country offices. The purpose of the organization is to serve as a neutral forum for all members of the United Nations through numerous international programs and initiatives. Due to this political neutrality, FAO has been able to act as a conduit for the completion of hundreds of international agreements covering food and agricultural matters.

One of FAO's activities involves the development of international codes and norms, such as the standards established for food processing in connection with Codex Alimentarius and the related conventions negotiated by the FAO/WHO Codex Alimentarius Commission and the Joint Expert Committee on Food Additives (JECFA). In a similar manner, FAO's Emergency Prevention System for Transboundary Animal and Plant Pests and Diseases (EMPRES) has provided the international framework for dealing with such agricultural plagues as the desert locust.

Another area of FAO activity is the gathering and dissemination of information on food and agriculture by means of databases organized under the umbrella of the World Agriculture Information Centre (WAICENT) in Rome. The center provides information to governments, research institutes, and universities, as well as to private individuals, using a wide range of media. This includes databases on soils and terrain (SOTER), information on soil and climate requirements for more than 1,700 plant species, domestic animal diversity information, lists of mutant plant varieties, a seed information system (SIS), a feed and forage database, a fertilizer yearbook, nutritional profiles of U.N. member countries, and vast amounts of material on food crops and crop shortages. FAO is also the world center for information on fisheries, aquaculture, and forestry.

The Food and Agriculture Organization has also become deeply involved in fighting world hunger and poverty by developing special programs for food security. This has involved a commitment to sustainable agriculture and rural development, the establishment of food cooperatives, seed saving programs at the small-farm level, land conservation, and an environmental agenda designed to better manage natural resources. FAO has taken this campaign to the public through its World Food Day programs in mid-October of each year. In 1997, FAO launched Telefood, a series of concerts and broadcasts designed to raise money for specific programs dealing with hunger and poverty. Money from these events, which are held in different places throughout the world each year, have funded over eight hundred small com-

munity-based projects in rural areas of such countries as Bangladesh, Somalia, Nepal, and Uganda.

**FARMERS' MARKETS.** Farmers' markets are common facilities or areas where several producers gather on a regular basis to sell various fresh meat, fruit, vegetables, and other food products directly to consumers. They circumvent the middleman and provide small- and medium-sized producers with an immediate, convenient, and economical sales outlet for their agricultural products. They are also established for the benefit of the urban consumer who values quality, variety, and freshness in food.

Farmers' markets vary greatly in terms of their physical shapes and configurations. The simplest form is the open-air market, where shelter is provided by the producers themselves or by structures already in place, such as bridges, arcades, and elevated highways. A more complex form is the market shed, which provides minimal protection from the elements yet allows easy access from all sides. The fully enclosed market house offers still greater shelter and facilitates year-round selling. Market districts, the most complex form, combine elements of the open-air market, the market shed, and the market house with other facilities, services, and related businesses.

Farmers' markets are an urban phenomenon worldwide and they assume characteristics determined by the social, political, and economic factors particular to their locales. The environment, natural features of the landscape, cultural norms, and the historic relationship between the countryside and the town also contribute to a wide range of market types. For example, the Tsukiji

## Image Not Available

Some markets open short-term retail space to local farmers in an effort to bring the producer and customer face to face. Amish farmers in Philadelphia's Reading Terminal Market often rent tables on Saturdays to sell their produce during harvest season. PHOTO COURTESY OF DAVID K. O'NEIL.

---

Market in Tokyo specializes in the wholesale and retail fish trade, with nearly 1,700 stalls covering a huge (54-acre/22-hectare) site. The market at Otavalo, Ecuador, is one of many open-air markets in South America, functioning as a principal trading point for Indian farmers selling local produce and handicrafts. And the daily market at Campo de'Fiori continues the long tradition of food marketing in one of the oldest public squares in Rome. Regardless of types or locations, farmers' markets around the world create a vibrant environment where consumers and producers are brought together for the benefit of the local community.

Although farmers' markets vary in terms of ownership and facilities, most operate by standard criteria in accordance with traditional trading ethics and standards. Vendors are subject to environmental, health, licensing, and other market ordinances and legislation. They must also adhere to the market's own rules and guidelines, which typically establish days and hours of operation, the payment of rents, and other business matters. A market

manager is usually engaged to oversee the daily activities of the market and to ensure that rules and guidelines are met.

The most important criteria for farmers' markets are that goods be locally produced and that vendors sell their own products. These criteria change over time and differ from place to place. "Locally produced" may be defined strictly in terms of the radius from the market, for example, thirty miles, but the actual distance depends on a number of circumstances. Farmers' markets near coastal areas may encompass a large radius that includes the source of locally caught fish. For markets in major urban areas, farms are of necessity some distance away, so the radius may be larger than that for smaller communities. Available transportation from farm to market as well as consumers' own perception of "local" may also influence definitions.

The other important criterion, that goods be the direct product of the merchant's labor, is again subject to different interpretations. In general it holds that fresh

Curbside farmers market in Dubuque, Iowa, circa 1900. COURTESY OF THE NATIONAL ARCHIVES.

meat and produce have been grown or finished on the producers' land. Cheese, honey, and processed meat products, such as sausage, are also produced on the vendor's land or at least within the defined radius of the market and with local ingredients. In general crafts and processed products using materials from outside the area of the farmers' market are excluded in favor of food products that have an entirely local origin. This restriction, however, is often lifted during winter months or when local products are not in season.

Farmers' markets belong to an ancient tradition of urban food retailing, in which the governing authority designated specific places for the exchange of life's necessities. Known as public markets, these places were intended to attract local and regional producers to the city to ensure citizens an adequate supply of healthful food at fair prices. They were critical to the survival of the town, because without them unbridled competition and unfair dealings in the sale of perishable food could jeopardize the public welfare. The local authority also maintained public markets to ensure a healthy population of workers, to prevent emigration, and to encourage agriculture near the city.

One of the most famous farmers' markets in nineteenth-century America was the city-owned High Street Market in Philadelphia. By midcentury this market con-

sisted of a series of sheds in the middle of High Street extending from the foot of the Delaware River to Eighth Street and again from Fifteenth to Seventeenth streets, with breaks only at the intersections. Space in the market was divided by types of goods, including meat, fish, garden seeds, produce, roots, herbs, vegetables, meal, locally produced earthenware, and New Jersey produce. The market was demolished in 1859, when it was replaced by a series of large, off-street market houses owned by private companies.

The majority of farmers' markets in the United States were municipally owned and operated until the mid-nineteenth century, when the movement for privatization generated alternative food-marketing establishments, including private shops and market companies. As a result, farmers' markets may be owned and managed by a municipality, but more often they convene on public property and are sponsored by nongovernmental entities, which may be farmers' associations, chambers of commerce, cooperatives, or other community organizations.

A quasi-public corporation, the Pike Place Market Preservation and Development Authority, oversees Pike Place Market in Seattle, Washington, one of the most successful markets in the United States. Established in 1907, the market encompassed a nine-acre historic district by the year 2000, with more than 100 farmers, 150

craftspeople, nearly 300 commercial businesspeople, 50 performers, and various services for low-income residents. During the 1990s the historic district hosted approximately 9 million visitors per year, and annual gross sales were estimated at \$9 million.

The number of farmers' markets has been growing steadily in recent years. Cities throughout the world are taking an interest in developing farmers' markets to add vitality to their public spaces, to redevelop their historic marketplaces, to revitalize neighborhoods, and to make fresh food available in areas underserved by supermarkets. In the United States, for example, the number of farmers' markets grew 63 percent in the last decade of the twentieth century, from 1,755 in 1994, when the U.S. Department of Agriculture began collecting data, to 2,863 in 2000. Other factors have contributed to their popularity. Most significantly, small farmers cannot afford to invest in the costly marketing systems required for mass food retailing and distribution. Direct access to the consumer therefore offers an alternative source of revenue and immediate cash flow.

Consumer demand for farmers' markets has also increased worldwide, primarily in response to the growing organic food movement and to public health disasters resulting from mass food marketing and production practices. Sophisticated consumers take a great interest in nutrition and wholesome eating habits, and they seek the sources of the foods they eat. As a result they view farmers' markets as healthy alternatives or supplements to supermarkets and other outlets of mass-marketed food. Farmers' markets devoted exclusively to the sale of organic food are abundant in France, one of the world's leading consumers of organic food. The demand for organic food markets, coupled with the larger international movement to resist the globalization of food marketing and production, will continue to foster farmers' markets as critical sources of fresh, healthful, and affordable food for the urban consumer.

**FAST FOOD.** What is termed "fast food" in the United States today most commonly consists of hot, freshly prepared, and wrapped food items, served to customers across a counter or through a drive-up window. Known as both "fast food" and "quick-service food" in the restaurant industry, these items are routinely sold and delivered in an amount of time ranging from a few seconds to several minutes; they now vary widely in food type, encompassing virtually all kinds of meats, preparation methods, and ethnic cuisines. Inexpensive hamburgers and french fried potatoes are still the products most readily identified as fast food, but the list of items sold in the format continually increases. Fried fish and shellfish, hot dogs, chicken, pizza, roast beef, and pasta are commonly sold at quick-service outlets. In addition to these staples, many quick-service restaurants sell a broad menu of Americanized Mexican, Greek, and Chinese foods. Some fast-food outlets offer specialty items, such as sushi, clams, or ribs, and others even sell complete "home-cooked" meals over their counters. Though menus and delivery formats vary greatly, fast food's chief common denominators include immediate customer service, packaging "to go," and inexpensive pricing.

The precise origins of fast food are vague, probably predating written history. Hungry people are as old as civilization itself, as are entrepreneurs eager to satisfy their hunger. Food vendors in ancient cities sold prepared items to passersby on the street. The actual foods varied greatly, depending on period and culture, but they generally comprised simple, inexpensive fare sold to people of modest means.

Immigrants brought a variety of food styles to America, often preserving these for decades as a comforting connection with their ethnic past. Though many immigrant foodways were elaborate and ritualistic, most groups had one or two simple items that they consumed on a daily basis. As a rule, immigrant groups preferred their indigenous grains: corn from the Americas, rice from Asia, and wheat from Europe. Often these served as the basis for the "peasant" foods of their homelands. Pasta and flat breads came over with Italians; tortillas, beans, and tamales arrived with northbound Mexicans; and Germans brought dark breads, along with a variety of fatty sausages (which later mutated into the hot dog).

Asian immigrants continued to eat rice as the basis of their diet.

In the early twentieth century fast food remained primarily the fare of the masses. Vendors wheeled their pushcarts daily to factory gates, selling their wares to hungry workers. Often catering to the tastes of the particular factory's dominant ethnic group, they charged customers pennies for basic items such as sausages, meatballs, or stew. Though popular among male industrial workers, this pushcart version of fast food never became mainstream cuisine.

The urban diner was the transitional phase between the vendor's pushcart and modern fast food. Most early diners were small restaurants, with limited seating, sometimes constructed out of converted railway carriages or streetcars. They served simple foods to working-class customers on a "short-order" basis, usually cooking each meal individually when ordered. Menus varied, but fried foods were common. Though diners often emphasized speed in delivering food, customers routinely lingered before and after eating.

The hamburger still stands out as the single most important American fast food, though the precise origin of this meat sandwich is the subject of historical disagreement. People have eaten chopped beef throughout the ages, and it was long a fixture in many world cultures. The lineage of the American hamburger seems to point directly, as its name indicates, back to the German city of Hamburg. First appearing on American restaurant menus in the mid-nineteenth century, ground beef patties bore the title "hamburg steak." By the century's close, vendors regularly sold meatballs wrapped in slices of bread at county fairs and summer festivals. Regional legends attribute the invention of this snack to several different individuals, but its true originator remains a mystery.

### The Rise of Modern Fast Food

Our modern image of the fast-food restaurant dates back to 1916, when Walt Anderson began selling "hamburger sandwiches" from an outdoor stand on a Wichita street corner. Anderson simply flattened a meatball and placed it between two halves of a bun. His sandwich quickly became popular, attracting long lines of hungry buyers. By 1921, Anderson had joined local insurance broker Edgar "Billy" Ingram to form the White Castle System. After opening several identical restaurants in Wichita during their first year, the partners quickly spread their business to neighboring cities, then to nine major urban areas throughout the Midwest and on the East Coast. What separated the White Castle System from earlier short-order restaurants was its very streamlined menu, comprising only hamburgers, coffee, Coca-Cola, and pie; a uniform architectural style; and strict standardization of food quality, preparation methods, and employee performance. By the close of the 1920s, White Castle's ag-

Fast foods have generated their own type of architecture. To attract attention and customers, some buildings were quite whimsical, like this 1930s hot dog stand. © CORBIS-BETTMANN.

gressive marketing and rapid spread had made the hamburger one of the most popular foods in America.

Other entrepreneurs soon noticed White Castle's success in the hamburger business. Very closely copying White Castle's products, architecture, and company name, competing new chains also thrived, carrying the hamburger craze across the nation to smaller cities and towns. The White Tower chain appeared in 1925, eventually challenging White Castle's dominance in several northern cities. Krystal's, opened in 1929 in Chattanooga, soon became the hamburger powerhouse of the southeastern states. White Castle's hamburger sandwich, along with its many imitators, became a daily staple for many working-class Americans. It proved so successful, in fact, that by 1930 the president of the American Restaurant Association identified the fast-food hamburger as the most important food item in the nation.

Hamburgers became even more a mainstream food during the 1930s. The larger restaurant chains began marketing their products to middle-class buyers, and even more Americans became burger lovers. Despite the harsh economy of the Great Depression, most fast-food chains continued to thrive, and in many cases grew considerably. Most continued selling the White Castle-style hamburger, but late in the decade the Big Boy chain spread east from California, introducing its new double-decker hamburger sandwich along the way. By the end of the Depression, America was a solidly hamburger-eating culture.

After prospering in the Depression, however, the fast-food industry suffered a serious setback during World War II. Shortages of necessary foodstuffs, such as meat, sugar, tomatoes, and coffee, meant limited menu offerings and often a significant loss of business. Attempting

to continue providing meals to their customers, fast-food restaurants experimented with different items that were still in abundance, including soy patties, chili, and french fried potatoes. Even more damaging than commodity shortages was the very low unemployment rate, which meant that most workers bypassed the restaurant industry in favor of higher-paying work. Adjusting to this labor shortage, chains soon replaced their all-male workforce with women and teenagers, two groups who would become their most common employees. Despite attempts to find palatable alternative foods, and despite the shifts in workforce, much of the fast-food industry was a casualty of the war; by 1945, more than half of America's restaurants had closed down, including several of the major fast-food chains.

Rebuilding the fast-food industry after the war proved a slow process. No single chain emerged to claim dominance, and little innovation occurred. Individual companies struggled to restore their prewar prosperity, and new regional chains tried to gain a foothold. Suffering the effects of escalating costs and still under the threat of continued shortages due to unstable food supplies in war-torn countries, fast-food restaurants often had to double prices to remain in business.

As population shifted from America's cities to suburbia during the 1950s, the fast-food industry quickly followed. Early chains such as White Castle and White Tower, resisting moving to the suburbs, were quickly eclipsed by upstart franchised chains. Burger King and McDonald's outlets became common fixtures at suburban crossroads, selling burgers, fries, and shakes to hungry families. Burger King's Jim McLamore and McDonald's Ray Kroc each sought to build one of his restaurants in every American town, and they opened hundreds of new Burger Kings and McDonald's each year in the 1960s. To accomplish this rapid expansion, they relied heavily on franchise investors, enforced strict product uniformity throughout their chains, and aggressively advertised in every newly opened territory. With McDonald's and Burger King's success, Burger Chef outlets soon appeared nearby. Arby's, Kentucky Fried Chicken, and Taco Bell were not far behind. By the late 1960s, fast food no longer meant just hamburger restaurants, but had diversified to include quick-service pizza, roast beef, chicken, and tacos. To give an idea of the dimensions to which the fast-food industry has grown, in 1999 Americans consumed over 26 billion pounds of beef, much of it as hamburgers. In that year McDonald's alone had more than ten thousand restaurants in the United States, from which it grossed in excess of \$13 billion in revenue.

### **Criticism of Fast Food**

Despite the widespread popularity of fast food in modern American culture, critics abound. Since the 1930s, articles and books have condemned the industry, exposing allegedly poor sanitary conditions, unhealthy food products, related environmental problems, and unfair work-

ing conditions. Whether it warrants the attention or not, the fast-food industry is still regularly cited for exploiting young workers, polluting, and contributing to obesity and other serious health problems among American consumers. American beef consumption, and more specifically the fast-food hamburger industry, is often blamed for the burning of the Amazon rain forests to make way for more grazing lands for beef cattle. Early foes of fast food cited the deplorable filth of many hamburger stands, in addition to claiming that the beef ground for their sandwiches was either spoiled, diseased, or simply of low quality. In fact, many critics maintained that much of the meat used in fast-food hamburgers came from horse carcasses. The high fat content of fast food was also controversial. Despite deceptive industry claims about the high quality and the health benefits of their products, in the 1920s and 1930s concerned nutritionists warned the public about the medical dangers of regular burger consumption. This distrust and criticism of fast food continue today, extending even further to include dire warnings about the industry's use of genetically modified and antibiotic-laden beef products. Most major chains have responded to recent attacks by prominently posting calorie and nutritional charts in their restaurants, advertising fresh ingredients, and offering alternatives to their fried foods. Despite a few more health-conscious items on the menu, fast-food chains now aggressively advertise the concept that bigger is better, offering large "super-size" or "biggie" portions of french fries, soft drinks, and milkshakes. Critics point to this marketing emphasis as a reason for an excessive and greatly increasing per-capita caloric intake among fast-food consumers, resulting in fast-growing rates of obesity in the United States.

Increased litter is another problem that critics have blamed on the fast-food industry. Selling their products in paper wrappings and paper bags, early outlets created a source of litter that had not previously existed. Wrappers strewn about city streets, especially those close to fast-food restaurants, brought harsh criticism, and often inspired new local ordinances to address the problem. Some municipalities actually forced chains to clean up litter that was imprinted with their logos, but such sanctions were rare. Fast-food wrappers became part of the urban, and later suburban, landscape. Since bags and wrappers were crucial in the delivery of fast food, the industry as a whole continued to use disposable packaging, superficially assuaging public criticism by providing outside trash receptacles for the discarded paper. Years later, environmentalists again attacked the industry for excessive packaging litter, criticizing both the volume and the content of the refuse. By the early 1970s, the harshest criticisms focused more on the synthetic materials used in packaging, and less on the carelessly discarded paper. Critics derided the industry's use of styrofoam sandwich containers and soda cups, claiming that these products were not sufficiently biodegradable and were clogging

landfills. Facing mounting opposition from a growing environmental movement, most of the major chains returned to packaging food in paper wrappings or small cardboard boxes.

Labor activists have criticized fast-food chains' tendency to employ inexpensive teenage workers. Usually offering the lowest possible wages, with no health or retirement benefits, these restaurants often find it difficult hiring adults for stressful, fast-paced jobs. Many critics claim that the industry preys on teenagers, who will work for less pay and are less likely to organize. Though these accusations may have merit, the industry's reliance on teenage labor also has inherent liabilities, such as a high employee turnover rate, which result in substantial recruiting and training costs. Companies have countered criticism about their use of teenage workers with the rationale that they offer young people entry-level work experience, teaching them: both skills and responsibility.

Despite the relentless attacks, hundreds of millions of hungry customers eat fast food daily. The media constantly remind American consumers about its supposed evils. Most are conscious of the health risks from fatty, greasy meals; most realize that they are being served by a poorly paid young worker; and if they choose to ponder it, most are aware that the excessive packaging causes millions of tons of trash each year. But they continue to purchase and eat fast food on a regular basis. Fast food remains central to the American diet because it is inexpensive, quick, convenient, and predictable, and because it tastes good. Even more important, Americans eat fast food because it is now a cultural norm. As American culture homogenized and became distinctively "American" in the second half of the twentieth century, fast food, and especially the hamburger, emerged as the primary American ethnic food. Just as the Chinese eat rice and Mexicans eat tamales, Americans eat burgers.

And fast food has grown even beyond being just a distinctive ethnic food. Since the 1960s, the concept has extended far beyond the food itself, with the term becoming a common descriptor for other quick-service operations, even a metaphor for many of the negative aspects of mainstream American life. Theorists and pundits sometimes use the term "fast food" to denigrate American habits, institutions, and values, referring to them as elements of a "fast-food society." In fact, "fast-food" has become a frequently used adjective, implying not only ready availability but also superficiality, mass-produced standardization, lack of authenticity, or just poor quality.

In the last two decades of the twentieth century, fast food gained additional economic and cultural significance, becoming a popular American export to nations around the world. Some detractors claim that it is even deliberately used by the United States, as a tool of cultural imperialism. The appearance of a McDonald's or Kentucky Fried Chicken restaurant on the streets of a foreign city signals to many the demise of indigenous cul-

ture, replacing another country's traditional practices and values with American materialism. In fact, the rapid spread of American fast food is probably not an organized conspiracy, rather more the result of aggressive corporate marketing strategies. Consumers in other countries are willing and able to buy fast-food products, so chains are quick to accommodate demand. Thought of around the world as "American food," fast food continues its rapid international growth.

#### CHRISTIANITY

Fasting or abstaining for a period from food and drink is common to various religions and is often an expression

Fasting was an integral part of Christian diet during the Middle Ages, but clever cooks devised numerous ways to create tasteful foods without meat or animal fats. These Polish fast-day dumplings are stuffed with mushrooms, a popular meat alternative. PHOTO BY ANDRÉ BARANOWSKI.

of penitence or mourning. Christian fasting and abstinence can be a purely personal matter or a social event at a special occasion, but it should be distinguished from the regular fasting that is prescribed by ecclesiastical authority and fixed on the Church calendar. The institution of fasting is a commandment for all Christians, and the Church's acceptance of it is thought to go back to Pope Calixtus I (217–222).

Fasting can be abstinence not only from food or drink, but also from sexual intercourse or other activities. This article focuses on food and looks at when Christians fast. Early monastic communities enforced abstinence from meat and wine, following in part the classical argument of Hippocrates and Galenus that warned against such “warm and humid” foods, which were thought to stimulate luxury. These strictures proved too severe—the religious lacked the energy to complete their daily tasks, and the laymen who worked outside the walls could not be expected to observe such stringent restrictions on food and drink.

By the tenth and eleventh centuries, the Roman Catholic Church had modified its rules for fasting, distinguishing between monastics and ordinary people, and regulating the severity of fasts on the Church calendar.

The Church never prescribed total fasts (without food and drink) or even those allowing just water and bread during a whole day or longer. Instead, several forms of the discipline were practiced, the more severe of which is called “fasting” and the milder “abstinence.”

During fasting periods, Christians were forbidden to eat the meat (and other products, such as milk and eggs) of quadrupeds and birds. Christians did not consider these animals and their products “unclean,” as did the Jews (Acts 10–16), but eating them was proscribed by the Church during certain times of the year. At such times, Christians fed on seafood, fish (including hard and soft fish roe), grains, and other field produce. The prohibition on dairy produce and eggs, in particular, and the resulting lack of protein nourishment, placed an enormous strain on medieval people. Chicken eggs were replaced by hard roe and butter, lard, and bacon by vegetable oil. For the European countries north of the Alps, where olives and almonds could not be grown, there was a substantial rise in the cost of living. Those who could afford them obtained expensive olive oil or almonds from the Mediterranean, which were mashed into a binding agent for sauces and chowders. Dried fruits, including dates, figs, raisins, and currants, from the Mediterranean were highly sought in northern Europe, as were the indigenous walnut and hazelnut.

During the milder periods of abstinence, milk could be consumed. It was not clear whether the meat from birds could be consumed during these times, but their eggs were permitted. Late medieval household accounts (fourteenth to fifteenth centuries) show that Christians lived according to these rules, especially during the longest fasting period in the church calendar, the forty weekdays of Lent or the so-called *quadragesima* (Latin *quadragesima* = 40, hence *quadragesima*), which precedes Easter, when the faithful switched over to a fish-and-oil kitchen.

In addition to Lent, the Catholic Church had four fasting periods called Ember days during the year (Latin *quatuor tempora* = four times, corrupted to *quatember*, then to “ember”). These days, prescribed by Pope Gregory VII (1073–1085), correspond to the turn of the seasons: the Wednesday, Friday, and Saturday of the week after St. Lucia (13 December) at the beginning of winter; then the Wednesday, Friday, and Saturday after Ash Wednesday (therefore, part of Lent) at the beginning of spring; next, the Wednesday, Friday, and Saturday of the week after Whitsuntide (Pentecost) at the beginning of summer; last, the same days of the week after Holy Cross Day (14 September) at the beginning of fall. Because the Christian calendar, unlike that of the Muslims, has a solar year with twelve months of more than the twenty-eight days of the orbit of the moon, these so-called Ember days always occur in the same season. Unlike the Muslim Ramadan, which shifts through the year, the Christian *quadragesima* always occurs during the turn from winter to spring.

In contrast to the *quadragesima* and the Ember days in which the severe abstinence that we call “fasting” was observed, a milder abstinence was obligatory all other weeks of the year on Wednesday and Friday, or Friday and Saturday, depending on the diocese in which one lived. On those days fish, which might be served with butter, was consumed. Fishermen strove to bring fresh fish to the market on those days, knowing that they would find ready consumers. Long after the fasting prescriptions in Catholic Europe had been mitigated by the Protestant Reformation of the sixteenth century, the habit of eating fish on Friday or Saturday remained common.

Religious generally did not observe a more severe fasting regimen than lay people, but the duration of the fast was greater. Monks and nuns started the *quadragesima* ten days prior to Ash Wednesday, thereby making a *quingagesima* of fifty days, and they also fasted on the Monday, Tuesday, and Wednesday before Ascension Day, the so-called Rogation Days. Advent, the four weeks before Christmas, formed a fasting period for them, not just the Ember days of St. Lucia that fall during this period.

The Rule of St. Benedict forbade the consumption of the meat of quadrupeds unless the religious was ill. The eating of birds was allowed, as was the consumption of eggs and dairy produce, except, of course, on fasting days. In this Rule it was stated that on fasting days, but not before Vespers, only one meal should be served that would be finished before dark. On other days, two meals were eaten, earlier or later depending on the season but always with daylight.

Mindful of the heresy of the Manichees and the Cathars, who taught that the body and the material world were the work of Satan and only the immaterial spirit was the work of God, Christians of the Western Church attempted to strike a balance between gluttony on the one hand and too rigorous an asceticism on the other.

The forty days of Lent referred to the forty years during which the Jews, under the guidance of Moses, had wandered through the desert before reaching the Holy Land (Deuteronomy 1:1–3), as well as to the forty days of Christ’s temptation by Satan in the desert (Matthew 4:1–11, Mark 1:12–13, Luke 4:1–13). But this does little to explain the timing of the Lenten fast, which commences at the turn of winter into spring. There is no text in the Bible prescribing this particular fast period. Also, the other Ember days coincide with the turn of the seasons.

Perhaps a key can be found in the reference to the humoral system of Hippocrates and Galenus, which was used to condemn the consumption of meat and wine as a stimulus of luxury. In this system of thought, every season has its own qualities—dry or humid, hot or cold—and the human body, which also has humoral qualities, needs a little digestive pause to switch over to another season. So fasting might have served such a function. This reasoning was seldom explicit, but in one example, a Latin

schoolbook of chronology from 1436 (*Computus Magistri Jacobi*), the comparison was made between the qualities of the seasons and the capital sins, from which the human mind should be cleansed by fasting.

However, not all questions concerning the Christian traditions for fasting and abstinence can be answered. Why was the longest fasting period the one from late winter to early spring? And why did the church not forbid the consumption of fish and seafood? Were there economic motives at stake—should eggs be allowed to hatch instead of being eaten by humans? Should the milk of animals be reserved for their newborn? Since Church authorities never clearly explained the reasons behind fasting and abstinence, we may never know the answers to these questions.

## HINDUISM AND BUDDHISM

### Hinduism

Food (in Sanskrit, *anna*) plays a very important role in the social and ritual life of the Hindus. Its importance is illustrated in a regular greeting at the Indian subcontinent: “Have you eaten?” is asked in the same way as people elsewhere might ask, “How are you?” Food is

Ceramic figurine of Chinese philosopher Lao-tse. Sung Dynasty, 960–1126 C.E. The bony, wasted body of Lao-tse, who flourished in the sixth century B.C.E., was a perennial symbol of abstinence and asceticism in Chinese culture. ROUGHWOOD COLLECTION. PHOTO CHEW & COMPANY.

mentioned in the early Hindu sacred writings known as the Vedas (Sanskrit, “knowledge”). In the Taṭṭirīya Upanishad it is written, “Food is life, therefore one should give food; eating is the supreme sacrifice.” Hindus have hundreds of traditional health rules, most of them regarding food and the preparation of meals. A traditional Hindu housewife spends a large amount of time cooking. Also religious books—such as the Dharmasāstras, the ancient “law books”—treat food and all that is related to eating extensively. Caste borders were sharpened by the many rules on eating, or rather not eating, together. In Vedic times (1500–500 B.C.E.), people ate everything, including beef, but in later times, probably under the influence of Buddhism, meat eating became a taboo, as was the killing of animals, either for food or for a sacrifice. One could argue that many of these food taboos were instigated by climatic conditions and by ideas about hygiene. Different groups and castes developed their own food rules, although there were regional differences. The Vaisnava community classifies food according to the three qualities (*guna*) of the Sāṃkhya philosophy: *sattva* food, which is pure; *rajas* food, which is energetic or exciting; and *tamas* food, which is impure. Only *sattva* food is allowed, which means no meat and fish, onions, garlic, specific fruits, and sharp spices.

Fasting in the sense of not eating for a specific time (*upavāsa*), or abstaining from specific substances during certain periods, is a well-established part of all Hindu spiritual practices. In the early times it was related to *tapas*, ascetic practices, and it is still a major aspect of the religious practices of many of the *sādhus* or “holy men” in India. Also, many ordinary Indians fast on specific days during the year, either by taking no food at all or by restricting their diet. For instance, Vaisnavas fast on the eleventh day of each half of the lunar month (*ekādaśī*), when they are only allowed to eat what has grown below the ground, along with dairy products. Before and during rituals, like sacrifices, but also before going on a pilgrimage, fasting and abstinence from certain food items are part of the practice of Hindus.

It is all part of the concept of *vrata* or religious vow. A *vrata* can be taken during a religious festival, or a pilgrimage, and also in conjunction with pursuing some goal in life, which may include material or spiritual well-being or success in business, love, or a good job. *Vratas* are applied following ritually significant and meaningful patterns, depending on which deity is addressed or which goal is pursued, or on a person’s station in life. Fasting and abstinence lead to the attainment of religious merit, which is then “used” to achieve the desired goal.

There is, however, also a spiritual aim: the control of the physical body as well as of emotions and the mind, which may lead eventually to the ultimate goal of unconditioned consciousness or liberation from the cycle of rebirth, in union with the transcendent (either considered personal or impersonal).

Complete fasting, in its most radical form, can be pursued until death, in which case it is called *prāyopavista* (“one who sits down and quietly awaits the approach of death” by not eating). Suicide through starvation has been well documented in Jainism, a religion that originated in the sixth century B.C.E., but Jain customs regarding this kind of suicide may be based on Hindu practices from around the fourth century B.C.E. Elderly people, who feel they are of no use any more to the community or feel they are a burden to the family, can choose this way of ending their lives. Suicide by ending the cycle of rebirth (*samsāra*) through not eating is beyond mainstream Hinduism, which sees it as another attachment that will even bring a worse rebirth unless the person has already been detached of all worldly concerns. A person can fast for a specific period to attain some goal, thereby pressuring family or community members, as exemplified by the fasting of Mahātmā Gandhi for political and humanitarian ends.

In the general practice of Hinduism, fasting and abstinence are not clearly distinguishable and are performed under the general concept of *vrata* or vow. The most common form of abstinence practiced by communities as a whole is vegetarianism. The consumption of substances that entail the killing of a living animal—in principle this

also includes eggs—is considered to create demerit, which has to be avoided at all cost by people belonging to those communities. Many others also practice vegetarianism as a spiritual practice by personal choice, either all the time, or even just one day a week.

Certain other substances are also avoided when a person performs a vow, because they are known to stimulate the senses, and therefore are contrary to the goal of control over the body and the senses. In particular, onions and garlic are avoided. For some groups or individuals this restriction is followed all the time. For others these foods are only avoided on certain occasions that call for a stricter diet. Especially on days that are set aside for rituals for ancestors, onions and garlic are forbidden.

*Vrata* or spiritual vow has three main branches. The first one is called *nitya*, which means permanent or always. Persons undertaking this type of vow are usually seeking the grace and blessing of a particular divinity toward a particular wish or desire (such as a good job, success at exams or business, or a good marriage). Hindus sometimes abstain from certain foods permanently. Or, they fast completely during one day of the week or month.

The second form of *vrata* is called *naimittika*, which means occasioned by some particular cause. It pertains to people who experience remorse or repentance in connection with a sin they have committed. They practice a vow in order to be relieved from the karmic consequences of their sin. The third type of vow is called *kāmya vrata*, which means a vow for what one desires. This form of vow is performed in order to achieve property, popularity, wealth, or health. An example of this kind of vow is called *somavrata*, which involves complete abstention from food on Mondays.

Vows follow many diverse patterns, depending on which deity is beseeched for blessing, the nature of the objective, or the wish that the devotee wants to see fulfilled. Such vows can require not eating, eating less, eating only certain substances, or avoiding certain substances altogether. The choice of the days on which or the periods during which the vow is performed is regulated by the ritual calendar.

The days of the week are ruled by the planetary deities and are also indirectly related to the main deities of Hinduism. People may choose to fast, or abstain from certain substances like meat or fish, or also from onions and garlic, on the day dedicated to the deity they are addressing with their vow. Sunday, *Ravivāra*, is ruled by *Sūrya*, the sun, and is dedicated to the achievement of victory, as in the case of disputes and court cases, but also when starting Vedic studies or a journey. Monday, *Somavāra*, is dedicated to *Candra*, the moon, and to *Śiva*. Fasting on Monday is directed to all general spiritual purposes. Tuesday, *Mangalavāra*, is dedicated to Mars, and *Kārttikeya*, *Śiva*'s son and the god of war. Fasting on Tuesday is directed toward victory, childbirth, and good

health. Wednesday, *Budhavāra*, belongs to Mercury. It is said that fasting on this day has twice the value of other days. It is mostly dedicated toward education and success in business. Thursday, *Brhaspativāra*, is dedicated to Jupiter, ruler over education and scholarship. Friday, *Śukravāra*, is ruled by Venus. Fasting on this day is dedicated to prosperity, marriage, and a harmonious family life. Saturday, *Śanivāra*, is ruled by *Śani* or Saturn. Fasting on Saturday will give the blessing of Saturn and longevity.

Another aspect that is important to the ritual calendar is the phases of the moon. One pattern of fasting and abstinence, which relates to the phases of the moon, starts on new moon day, when the practitioner eats fourteen hands full of food. Then every next day one eats one handful less, until on the day of the full moon one eats nothing at all. During the waning moon one eats again one handful more each day, until the vow is completed on the next new moon day, when again fourteen hands full of food are eaten.

Generally, all kinds of vows of fasting and abstinence are practiced on the occasion of the many religious festivals celebrated during the course of the year, and also on the occasion of the Hindu rites, which are related to specific stages in life, such as birth, name-giving, first eating of solid food, puberty, the beginning of Vedic studies, marriage, and cremation.

On the other hand, certain foods are especially dedicated to certain deities. Such foods are regularly prepared at home and offered to the deity as part of certain festivals or during home worship, after which they are enjoyed by those present, and often also sent to relatives and friends. These special foods are also prepared and offered as part of the daily temple worship. After being offered to the deity, they are distributed as *prasāda* or sanctified food among the worshipers and visitors. Examples of such special food are rice prepared with black pepper and cumin fried in clarified butter or ghee, which is dedicated to *Śiva*; *laddu* or sweet balls for Krishna and Ganeśa; or rice prepared with tamarind, which is specially offered to Visnu. A person can also make a vow in connection with a certain deity to eat only the deity's special food for a period of time.

Some examples of this kind of *vrata* include twenty-one days of drinking only milk, or eating only the leaves of the bilva and banyan trees, after dipping them in water, a vow dedicated to *Śiva*. A fasting vow that is dedicated to Ganeśa is practiced from the day after the new moon in the month of *Kārttika* (October–November), through the sixth day of the waxing moon in the month of *Mārgaśīra* (November–December), which means complete fasting for three weeks. Those who follow this vow are given a yellow thread bound around their wrist, a *raksabandha*, worn on the right wrist for men and on the left for women. On the concluding day they give a donation of money to a priest as well as food, and then

they eat again. A vow for the goddess Devī involves complete fasting on the Friday in the month of Caitra (March–April). During the day the practitioner meditates on the goddess. The person concludes by offering *jagari*, which is raw sugar from sugarcane. After this worship one eats again. A vow dedicated to Visnu is called Vaikuntha *caturdaśī* and involves complete fasting on the fourteenth day of the waxing and waning moon.

One other place where fasting is given great importance within the many traditions and practices of Hinduism is in Ayurveda and Siddha medicine. According to these traditional healing methods, fasting is considered one of the great medicines. Both apply fasting for the cleansing and balancing of the physical body, as well as for the emotions and the mind. Here three kinds of fasting are distinguished: purification fasts to clean the system; healing fasts to overcome a specific disorder; and austerity fasts, which are undertaken to deny the bodily urges on the way toward liberation from the cycle of rebirth.

### Buddhism

According to the Buddhist tradition, Siddhārtha Gautama, the Buddha, lived between 560 and 480 B.C.E., although recent research indicates that he may have lived about a hundred years later. In that period northeast India was being transformed from a agricultural society to a more complex urban society. The ancient religious traditions of early Brahmanism no longer fitted the needs of society and of individuals. Therefore, many left society to find new religious ways, mostly by practicing asceticism. The Buddha was one of them. The Buddha used traditional ascetic practices including a very strict fast, reducing his intake of food to a few drops of bean soup a day. This starvation almost killed him, and he became aware of the fact that the body should not be ignored to arrive at man's spiritual core, but should be supported in a healthy and moderate way: no consciousness without a body; no experience of liberation or *nirvāna* without a body. After his "awakening" (*bodhi*) he formulated his "middle path," holding the middle between extreme asceticism and indulgence. This is the reason why fasting and abstinence in Buddhism are always placed within the context of the middle path.

In Asian as well as in Western Buddhist communities, certain traditions regarding food are followed in which there is a difference between the customs of laypeople and the stricter rules for monks and nuns. In general, Buddhists prefer to abstain from eating meat, since this involves the killing of living beings, although, even for the monks and nuns, there is no rule forbidding the eating of meat, unless the monk or nun, who is provided with a meal by a layperson, knows that the animal has been specially killed for the occasion. According to the monastic rules, the Vinaya, monks and nuns should have only two meals a day, in the early morning and before noon, and abstain from food for the rest of the day. One

of the reasons is that meditation practice is considered to be difficult if the stomach is full. On festive days, especially at full and new moon, and during meditation retreats, laypeople regularly follow those rules too. In lay Buddhist practice, the Hindu custom of sharing "sanctified" food or *prasāda*, food that is pure (no meat or sharp spices) and has been offered to monks and nuns or to statues of the Buddha or Buddhist deities, is also followed.

In the Buddhist practices of the Newars in the Kathmandu Valley, one finds observances, *vrata*, similar to those of the Hindus, in which fasting takes a prominent role, for example, in the observances connected with full and new moon, but also in those directed to a specific deity; for example, on the eighth day after full moon the fasting is held to honor the bodhisattva Avalokiteśvara-Lokeśvara, the embodiment of compassion. During public or private ritual performances fasting is observed to maintain purity. And, similar to the Hindu custom, an observance is also a way to achieve a specific spiritual or material goal. Some examples include the fasting for Lokeśvara, which is supposed to cause the birth of a son; a fast for Tārā, which frees one from illness, dangers, pain, and untimely death; a fast for Hārītī protects against smallpox; and other deities are invoked by following rules of purity, including abstaining from sex, and fasting for good jobs, before an exam, or before going on a journey.

### ISLAM

The fast of the month of Ramadan is one of the five major obligations of individual Muslims (the other four being the pronouncement of the confession of God's Unity, the five daily prayers, the religious tax, and the pilgrimage to Mecca). The Qur'an, the holy book of Islam, charts a middle position—"Thus we have made you a community of the middle path" (2:143)—between the ascetic ideal of Christian monastic practices and the more materialistic style of Jewish religion. Islamic fasting during Ramadan is quite harsh by Western standards and in-

cludes a full month of total abstinence from food and drink during the hours between dawn and sunset, although the evenings are a time of joy and celebration. The period of fasting during Ramadan is not an individual religious exercise, but part of a great social event that binds individual Muslims collectively.

The Qur'an explains the significance of this time of prayer and abstinence. During the Medina period, which marked the last ten years of the life of the prophet Muhammad (570–632 C.E.), Muslims were instructed to join the Jews in prayer in the direction of Jerusalem, to the north. After the Jews of Medina refused to recognize Muhammad as a prophet and obstructed his ideal of an Islamic state, the Prophet received a revelation that his followers should turn to the Ka'aba of Mecca (to the south of Medina). The Qur'an (2:183–187) prescribes fasting during the month of Ramadan, but prior to Muhammad's revelation, followers observed the fast of the day of Atonement or Ashura, as did the Jews. The institution of the Ramadan fast marked a return to an older Arab tradition that included abstaining from warfare and blood feuds. (In the same chapter of the Qur'an a third Arab institution was restored and reinterpreted: the pilgrimage to Mecca [2:196–203].)

The fast of Ramadan was reinterpreted as an instrument for the forgiveness of sins. It was instituted in commemoration of the Prophet's first revelation, which occurred during that month (on the twenty-first, twenty-third, twenty-fifth, and twenty-seventh of Ramadan) and in awareness of God's decision about man's fate for the coming year. From dawn—in fact, from the moment when a black thread can be distinguished from a white one—until sunset nothing may enter the body through any of its parts. Therefore, not only are eating and drinking forbidden, but also the use of fragrant perfume and even sexual intercourse. Women who menstruate during this period are not allowed to observe fasting but must make up for the days they miss by fasting later on.

In the first generations after Muhammad the basis was laid for what is known as the *shari'a* or Islamic law. Scholars during the first century after Muhammad developed the rules for determining the beginning and end of the month of Ramadan. It is commonly accepted that some part of the new moon must be “seen” (physically or intellectually, i.e., directly observed or by calculation), although there is a divergence of opinion among Muslim communities concerning the correct method for defining the start and finish of the month of Ramadan. Travelers and those who are sick are excused from the fast, but even these exceptions are disputed, as are the various compensations for some days of fasting or the alms given to the poor.

In addition to the month of Ramadan, there are voluntary days of fasting for Muslims, such as the tenth day of Muharam (Ashura, a continuation of the Jewish day of atonement, although the Islamic lunar calendar does not

Bakers in the Old City of Jerusalem are selling holiday bread for Ramadan. PHOTO COURTESY OF AP/WORLD WIDE PHOTOS.

coincide with the solar calendar of Jews and Christians). For the very pious there is a voluntary fast on all Mondays and Thursdays.

Fasting not only constitutes abstinence from food. Pious Muslim preachers stress that fasting is more an exercise of the mind than of the body. The prophet Muhammad said, “He is not a good Muslim who eats his fill and leaves his neighbor hungry” (Glassé, p. 112). The mystical theologian al-Ghazali (d. 1111) proposed a category of fasting that included “other parts of the body” (besides the mouth and the sexual organs): The eyes and the hands should be kept under control and prevented from evil. Attention must be given to the poor during the month of Ramadan, and the special “alms tax” (*zakat fitra*) or “gift of breaking the fast” consists of 2.5 kilograms of rice or the equivalent in money given to the poor. Slander and gossip in particular are forbidden during Ramadan, and a saying from Muhammad supports this admonition: “If one does not give up saying false words and doing false deeds in Ramadan, giving up eating and drinking means nothing to Allah” (Buitelaar, p. 22).

Some preachers suggest that the daily fast should be followed by a light meal only and by many prayers. A folk custom ends a day of fasting in the manner of Muhammad: Commonly, a Muslim eats a date first, following the example of the Prophet. In countries where fresh dates are not available, they are imported from abroad to facilitate this custom of the believers. It is also quite common for Muslims to invite friends and relatives to their homes on certain days so that they might experience this rewarding moment together after a full day of fasting: breaking the fast together with a first light meal (*iftar*, literally meaning the breaking snack), accompanied by the pious words of a preacher.

Local kitchens serve a great variety of dishes during the evenings of Ramadan. In the Indonesian province of

Aceh, known for its devout Islam, believers eat *beras tape*, a porridge of fermented sweet rice, as their first snack after a day of fasting. Because of the process of fermentation, this snack contains a significant amount of alcohol, but it is considered a traditional food, not a drink, and is therefore acceptable to pious Muslims. Fish is not considered a good choice for Ramadan meals because it is too light and does not provide a good base for the next day of fasting. A tomato soup (*barira*) that is prepared with a variety of vegetables and beef, buffalo, or lamb is much more substantial and provides longer-lasting nutrition. In countries of the Middle East it is closely identified with the celebration of Ramadan. Sometimes before dawn a heavy "breakfast" (*sabur*) is consumed in preparation for a full day of fasting. Buitelaar mentions (p. 47) a daily meal of rabbit that is eaten at 3:00 A.M. in Morocco.

After Ramadan, on the first day of the month of Shawwal, the so-called small festival is celebrated. A major festival also occurs on the tenth day of the month of the *hajj*, when the sacrifice of Abraham is recalled, but the end of Ramadan brings the greatest joy to Muslims: Relatives are visited and many types of sweets are consumed. In Turkey, this celebration is known as the sugar festival, a celebration also marked in recent decades in parts of Europe where Turkish migrants have settled.

Some mystical or local groups have developed special kinds of fasting, which are either not generally accepted or even denounced by other Muslims. In order to obtain special favors from God, Muslims in Indonesia, especially on the island of Java, practice the *mutiban*, or "white fasting." Muslims there only eat white rice and boiled eggs, and they drink plain ("white") water during a certain period, often to implement a vow. Members of the Khalidiyah branch of the Naqshbandiyah brotherhood practice *suluk* (spiritual travel) or *khalwat* (loneliness), a forty-day period of abstinence from meat and some other dishes; believers also refrain, as much as possible, from talking. Their opponents blame them for introducing a Christian habit (forty days of fasting, and abstinence from meat) into a well-defined Muslim regulation.

The Islamic rules on *haram* (forbidden) foods and drink, such as pork and wine, are not considered akin to the pious acts of fasting or abstinence, but rather are part of the regular observance of taboos and are therefore beyond the scope of this entry.

In many regions and during different periods of Muslim culture, ascetic and mystical movements have introduced elements of abstinence, some from sexual intercourse, others from various luxuries such as perfumes during certain periods. For the especially pious and for those who make special vows, milk and meat are avoided, and there are even vows of abstinence from sleep.

In modern Muslim communities, both in countries with Muslim majorities and also in the new Muslim diaspora in Western countries, the fast of Ramadan is one of the most carefully observed aspects of Islamic custom.

Even among secularized Muslims, who do not say their prayers five times each day or who only very seldom join the Friday prayers, there is an attempt to keep the fast for part of the month of Ramadan, as a way of keeping in touch with their spiritual and cultural roots. As with those who are more devout, the festive moment in which the fast is broken is a central element. In 1963 Ahmad Hasan al-Zayyat, the editor of the journal of the Al-Azhar mosque and university in Cairo, commented bitterly on the way of fasting: "We do not have any more thirty days of fasting, but thirty days of breaking the fast" (Goitein, p. 108). This comment may reflect the general practice of fasting and abstinence found in Islamic culture, where a middle path has been found: between strict religious and cultural interpretation, between individual piety and communal belief. The middle path of Islamic fasting and abstinence lies between ascetism and pure materialism.

## JUDAISM

The phenomenon of fasting in the variegated history of Judaism has its roots in the biblical text. Though it is not entirely clear why and when this practice arose, it is certain that in ancient Israel, abstaining from food and drink on both the individual and communal level was considered an act of piety that one would (in most cases spontaneously) undertake as a means of entreating God's compassion or in the hope of averting divine punishment (Judges 20:26; 1 Kings 21:9, 27; 1 Sam. 7:6; 2 Sam. 12:16, 22; Jer. 14:12, 36:6, 9; Joel 1:14, 2:12, 15; Jonah 3:5; Ps. 35:13, 69:11–12; Esther 4:16; Dan. 9:3; Ezra 8:21, 23; Neh. 1:4; 2 Chron. 20:3) or as a sign of mourning and lament (1 Sam. 31:13; 2 Sam. 1:12; 12; Zech. 7:5; Esther 4:3; Ezra 10:6; Dan. 10:2–3; 1 Chron. 10:12).

#### Fixed Fasts

The four fixed fast days mentioned by the post-exilic prophet Zechariah relate to calamities centered about the

destruction of Jerusalem and the Temple (Zech. 8:19): the fast of the fourth month corresponds to what is celebrated as the seventeenth of Tammuz, which marks the breaching of the walls of the city (in 2 Kings 25:4 and Jer. 39:2 the date is the ninth); the fast of the fifth month, the ninth of Av when the Temple was destroyed (in 2 Kings 25:8 and Jer. 52:12–13 the date is the tenth); the fast of the seventh month, the third of Tishrei when Gedaliah, the Babylonian-appointed governor of Judah, was murdered (2 Kings 25:25, Jer. 41:1–2); and the fast of the tenth month, the tenth of Tevet, which marks the beginning of the siege of Jerusalem by Nebuchadnezzar, king of Babylon (2 Kings 25:1–2, Jer. 52:4). The custom to fast on the thirteenth of Adar, the day before the holiday of Purim, which celebrates the downfall of Haman and the redemption of the Jewish people, does not commemorate a tragedy in Jewish history but rather stands as a reminder of a precarious moment when disaster was averted (Esther 4:16).

By contrast, the Day of Atonement, Yom Kippur (celebrated on the tenth day of the seventh month, which is enumerated as the first month of the new year), the one fast specified in the Pentateuch, is part of the afflicting of the body—according to later rabbinic law this comprises five forms of self-denial: abstention from eating, washing, anointing, wearing shoes, and cohabitation; Mishnah Yoma 8:1—that is a means of purification from transgression (Lev. 16:29–34, 23:27–32; Num. 29:7–11). From other verses we can deduce that refraining from eating and drinking was considered one of various methods of abstinence by which one could afflict the body, acts that were often accompanied by oaths and vows (Num. 30:2–16; Dan. 10:12). There is evidence to suggest that fasting was also practiced as preparation for communing with the spirits of the dead (1 Sam. 28:20). The narrative about Moses being with God for the forty days in which he wrote the tablets of law specifies that during that time he neither ate bread nor drank water, indicating that he was in a transformed state wherein the normal physical needs could be discarded (Exod. 34:28; Deut. 9:9, 18), a theme that is applied as well to Elijah when he had the theophany on Horeb, the mountain of God (1 Kings 19:8–12). In the case of Daniel as well, acts of prayer, which included fasting, were answered with a vision of the divine (Dan. 9:20–27, 10:7–21).

Abstention from food was considered one of the several typical acts of humbling oneself, which may have included renting one's clothes, lying in sackcloth, walking about in a subdued posture, sleeping on the floor, and not washing, anointing, or changing one's clothes (2 Sam. 1:11–12, 12:16–20; 1 Kings 21:27; Jonah 3:5; Ps. 35:13, 69:12; Esther 4:3; Dan. 9:3; Neh. 9:1). Fasting could also accompany weeping and the offering of sacrifices (Judges 20:26; Joel 2:12) or the confession of one's iniquities (1 Sam. 7:6; Neh. 9:2; Dan. 9:4), but on occasion it takes the place of the sacrificial cult (Joel 1:13–14). The purpose of fasting as a ceremonial expression of remorse and

supplication is underscored in the prophetic pronouncements against those who would fast without the proper intent as if God demanded of the Israelites external forms of self-affliction without commitment to act justly (Isa. 58:3–7; Jer. 14:12). Indeed, according to the messianic declaration of Zechariah, the fast days in Israel commemorating past suffering centered around the destruction of Jerusalem and the Temple would be transformed into occasions for joy provided there would be love of honesty and integrity (Zech. 8:19).

Fasting without repentance is of no value. In the Second Temple period, abstaining from eating and drinking continued to serve as a primary means of atonement, but in addition we have evidence that on occasion it functioned as an ascetic regimen that served to purify the heart and bring one closer to God, and even in some cases to induce an ecstatic state wherein a supernatural vision was granted (2 Bar. 12:5, 20:5–6, 43:3; 4 Ezra 5:13–20, 6:35–36). There is evidence from the rabbinic corpus that select individuals similarly fasted excessively in order to have visionary experiences (Palestinian Talmud, Kil'ayim 9:4, 32b), a phenomenon attested as well in the Heikhalot literature, the magical and mystical texts that began to take shape roughly during the time that Judaism and Christianity began to emerge as distinct liturgical communities. We know little about the social background of the individuals responsible for these texts, but we can conclude with some degree of certainty that they adopted ascetic practices, primarily fasting and sexual renunciation, as preparation for dream-vision, angelic adjuration, or heavenly ascent. In the tenth century, a leading rabbinic figure, Hai Gaon, summarized these older practices by saying that anyone who wished to gaze at the chariot must “sit fasting for a specified number of days, place his head between his knees, and whisper to the earth many prescribed songs and hymns.” It is likely that fasting or even a restricted diet (together with sexual abstinence) was viewed as means by which the human could be transformed into an angelic being, a prerequisite for the attainment of the visionary encounter with an angel or the glory.

Perhaps some of the rabbis developed a critical stance vis-à-vis fasting as an appropriate form of piety to combat such individuals and their anomian customs. Thus, a dictum is transmitted in the name of R. Yose: “An individual is not permitted to torment himself in fasting lest he fall upon the community and they will need to support him” (Tosefta, Ta'anit 2:12). According to another statement attributed to Samuel, “Whoever sits in a fast is called a sinner” (Babylonian Talmud, Ta'anit 11a). In the words of a maxim ascribed to Reish Laqish, “the scholar is not permitted to sit and fast for it diminishes the work of heaven” (Babylonian Talmud, Ta'anit 11b). Finally, Rav reportedly declared that “in the future a man will have to give an account for everything that his eye saw but he did not eat” (Palestinian Talmud, Qiddushin 4:12, 66b).

An especially interesting concern for the rabbis was the abstinent woman whose constant fasting “causes her to lose virginity” (Palestinian Talmud, Sotah 3:4, 19a). Indeed, on account of the reduced intake of food she is called the “fasting virgin,” a term that suggests that the challenge such a woman posed was that she disrupted the societal expectations by abdicating the domestic responsibility of child bearing. In contrast to early Christianity where virginity and fasting were considered virtuous acts of piety, the rabbinic sages castigated the woman who adopted an ascetic lifestyle with regard to sexuality and eating. According to one rabbinic ruling, the ascetic woman is enumerated among those who bring destruction to the world (Mishnah, Sotah 3:4), an expression meant to convey that female celibacy results in the breakdown of marital life and the bearing of progeny.

### Additional Fasts

The basic approach to fasting was continued by the rabbis who, in their characteristic fashion, codified specific regulations to fashion the biblical references into binding rituals. In addition, the rabbis decreed additional fasts in the course of the calendar, generally associated with the fixed fasts and other calamitous events in biblical and postbiblical history. Yet, the rabbinic authorities were opposed to extreme forms of abstinence, including fasting, as we find, for instance, in the Therapeutaue community described by Philo, early Christian communities, and the individuals whose experiences are preserved in the Heikhalot texts. It must be pointed out, however, that the rabbinic sources themselves yield proof that some members of the academies were more positively disposed toward voluntary abstinence as a way to cultivate the highest form of piety. Thus, there is substantial textual evidence to indicate that sages (many from the third and fourth centuries) undertook excessive fasts as part of an ascetic lifestyle, to attain an extraordinary experience (usually of a visual nature), or for penance (Palestinian Talmud, Kil’ayim 9:3, 32b, Ta’anit 2:13, 66a, Nedarim 9:2, 40d; Babylonian Talmud, Pesahim 68b, Hagigah 22b, Qiddushin 80b, Baba Metsi’a 85a, Nazir 52b).

Additionally, there is verification that some rabbis preserved an ancient custom, apparently initiated in the land of Israel, to fast every week on Monday and Thursday (Palestinian Talmud, Ta’anit 1:6, 64c; Babylonian Talmud, Shabbat 24a, Ta’anit 12a), and there is as well confirmation of the fact that some considered fasting appropriate for Sabbath (Babylonian Talmud, Pesahim 68b, Beitsah 15b) even though others clearly thought the opposite and prohibited fasting on Sabbath (Palestinian Talmud, Ta’anit 3:13, 67a, Nedarim 8:10, 40d), maintaining that Sabbath is a day of joy and rest, the sanctification of which involves physical pleasure, encompassing eating and drinking (Palestinian Talmud, Shabbat 15:3, 15a; Babylonian Talmud, Berakhot 32b). A residue of the former orientation is found in the ruling that fasting because of a troubling dream (*ta’anit balom*) is allowed even on

Sabbath (Genesis Rabbah 44:12; Babylonian Talmud, Berakhot 31b, Ta’anit 12b). Interestingly, the routine of fasting on Sabbath was revived in the twelfth and thirteenth centuries by figures like Judah he-Hasid, the leader of the Rhineland German Pietists (Hasidei Ashkenaz), who adopted an ascetic form of devotion, and we even have a report by Avigdor ben Elijah ha-Kohen that Judah fasted on Rosh Hashanah, the Jewish New Year, a practice followed by other rabbis connected to this group, such as Abraham Haldi of Bohemia, though by no means accepted by everyone. Finally, there are rhetorical flourishes in rabbinic literature that assign supreme theurgical significance to fasting as a means of atonement. Perhaps the best illustration of this approach is the prayer offered by Rav Sheshet before God, which is predicated on the symbolic equation of fasting and sacrifices: “May it be your will to account my fat and blood, which have been diminished, as if I sacrificed them before you on the altar, and you should find favor with me” (Babylonian Talmud, Berakhot 17a).

In spite of the admonitions against excessive fasting, it must be said that an ascetic tendency is well entrenched in the classical rabbinic corpus, an orientation that served as the foundation for pietists and mystics at later stages of Jewish history. In particular, the Rhineland Pietists and the Provençal and Spanish kabbalists of the twelfth and thirteenth centuries cultivated ascetic practices to attain a state of holiness and removal from the bondage of the corporeal world, in part based on earlier mystical tracts. An especially important part of the pietistic regimen was fasting, which, together with sexual abstention, was viewed as the mechanism by which the mortal being could be transmuted into an angel. For example, Eleazar of Worms, another leading member of the Hasidei Ashkenaz, chronicles an elaborate ceremony for the transmission of the divine name, which involved ritual immersion, being clad in white clothes, and fasting. Acts of self-denial and self-affliction were considered to be the way of fulfilling the hidden will of God.

### Kabbalistic Piety

In kabbalistic literature as well we find a central concern with fostering an ascetic piety predicated on acts of behavior that transform the human into an angel. Moreover, kabbalists articulated a contemplative goal of union with God, which is often described as the merging of the finite and infinite will, as we find in Azriel of Gerona, Jacob ben Sheshet, and the authors of the Zohar. The rabbinic analogy comparing fasting to sacrifice played a crucial role in shaping the mystical sensibility of offering one’s heart fully to God and subjugating desire (Zohar 2:20b, 119b, 153a). From the symbolic vantage point endorsed by kabbalists, fasting is the instrument by which one becomes a sacrifice and is submerged thereby in the Godhead. In somewhat different terminology, but expounding a similar ascetic ideal, in zoharic literature the members of the mystical fraternity engaged in Torah

study are said to partake of the spiritual food that angels eat, the “bread of the mighty” (*lehem 'abirim*) (Ps. 78:25), the overflow of divine wisdom, rather than the coarse food of this world (Zohar 2:61b). With this idea we reach the paradoxical reversal characteristic of mystical insight: abstention is genuine consumption.

Utilizing an older midrashic gloss (Leviticus Rabbah 20:10) on the verse “And they saw the God of Israel, and they ate and drank” (Exod. 24:11), the kabbalists affirm that this refers to an “actual eating,” which does not entail physical ingestion, but deriving sustenance from basking in the visual presence of God, a state applied to the righteous and angels in the world to come (Zohar 1:104a, 2:126a). By fasting the kabbalist anticipates that condition in this world and thus has a foretaste of the food that is perpetually fulfilling.

**FATS.** Fat is a generic term for triacylglycerols, which are a class of structurally similar chemical compounds that contain three fatty acid molecules that are linked or chemically esterified to one glycerol molecule (Figure 1). Mammals store triacylglycerol as lipid droplets in specialized cells referred to as adipocytes, which compose the white or yellow tissue known as adipose or neutral fat tissue. White fat has several functions in mammals. It is a reservoir for storing excess energy obtained from the diet. Fatty acids are a dense storage form of chemical energy in mammals. Adipose tissue also has an important role in padding and thereby protecting various organs throughout the body from temperature extremes and

physical impact or trauma. Triacylglycerol, when converted to phospholipid, is a primary constituent of cell membranes and therefore is critical for all forms of life. Mammals also contain brown fat in various locations throughout the body including the neck, thorax, and abdomen. Brown fat functions to generate body heat and therefore it is an important tissue for energy expenditure, otherwise referred to as “burning calories.” Brown fat can generate heat because it contains mitochondria with a unique and specialized function. In most other cells, mitochondria are the energy-producing compartments in the cell that generate adenosine triphosphate (ATP), which is a chemical form of cellular energy that is required for numerous cellular chemical reactions. In brown fat, the energy generated by mitochondria is used to generate heat. Brown fat cells contain an “uncoupling” protein that diverts energy away from ATP synthesis and toward heat production. Energy utilization by brown fat is tightly regulated by signals it receives from the sympathetic nervous system. Animals that are adapted to cold temperatures display increased heat production from brown fat, and brown fat is proportionally more abundant in infants than in adults.

#### Classes of Fatty Acids

Fatty acids are a diverse family of structurally similar carbon chains that contain a single carboxylic acid group (see Figure 1). Fatty acids differ from one another by their carbon chain length, which is usually an even number of carbons that can exceed twenty carbon atoms. Fatty acids are often categorized as short-chain, medium-chain, or long-chain fatty acids because each of these groups displays distinct physical properties. Short-chain fatty acids contain up to seven carbon molecules and are liquids even at cold temperatures. Medium-chain fatty acids, which contain between eight and twelve carbons, are liquids at room temperature but solidify when refrigerated. Long-chain fatty acids contain greater than twelve carbons and are solids at room temperature, but liquefy at elevated temperatures. Long-chain fatty acids are the most abundant fatty acids in plant and animal foods. Short-chain fatty acids are found in whole cow’s milk, and medium-chain fatty acids are abundant in coconut milk.

Fatty acids also differ by the number and location of carbon–carbon double bonds, otherwise called the degree of saturation. Saturated fatty acids do not contain any carbon–carbon double bonds because all carbon molecules are “saturated” with hydrogen molecules. The most abundant saturated dietary fatty acids are palmitic and stearic acids, which are long-chain fatty acids found in foods derived from animals and are abundant in meat and dairy products (Table 1; see Figure 1). Monounsaturated fatty acids contain a single carbon–carbon double bond (see Figure 1). Oleic acid is a monounsaturated fatty acid and a common dietary component found in canola and olive oil. Polyunsaturated fatty acids contain up to six carbon–carbon double bonds that are always separated by

The fatty acid composition of triglycerols found in mammals is usually complex and is influenced by the fatty acid consumed in the diet and by the tissue where it re-

## Essential Fatty Acids

Rodents placed on a fat-restricted diet are growth impaired, infertile, and develop lesions in the skin and kidney. These pathologies are not observed if the diet is supplemented with linolenic (omega-3) and linoleic acid (omega-6). The results of these studies indicated that mammals cannot synthesize these fatty acids and therefore that these fatty acids are essential components of a healthy diet. Human deficiencies of these essential fatty

acids are rare but can occur in infants and children or as a result of intestinal absorption disorders. Human essential fatty acid deficiency compromises liver function, results in unhealthy skin, and impairs growth and development in infants including impaired cognitive function, visual acuity, and hearing.

Essential fatty acids are necessary to maintain the architecture of cell membranes and the integrity of the skin. They are also precursors for the synthesis of eicosanoids ("eicosa" meaning twenty carbons in length), which are bioactive, hormone-like compounds derived from linoleic and linolenic acid. The eicosanoids include prostaglandins, which elicit numerous and varied biological responses including induction of labor, regulation of the female reproductive cycle, and modification of pituitary function. Thromboxane is an eicosanoid that functions in platelet aggregation and blood clotting; leukotrienes function in the inflammation and allergic responses. The omega-3 fatty acid alpha-linolenic acid is also a precursor for eicosapentaenoic acid (EPA) and docohexaenoic acid (DHA) synthesis. Both DHA and arachidonic acid are important for nervous system and retina development. DHA may be an essential dietary fatty acid for preterm infants because studies indicate that it is not synthesized in sufficient quantities to meet the infant's needs.

There is no Recommended Dietary Allowance (RDA) for essential fatty acids. The minimal adequate adult intake of omega-6 fatty acids is estimated to be 2 to 4 g/day of linoleic acid. Americans normally consume about 10 to 15 g/day. The minimal adequate adult intake of omega-3 fatty acids is estimated to be 0.2 to 0.4 g/day, but intakes as high as 3 g/day may have added benefit. Omega-3 fatty acid intakes should be increased during pregnancy and lactation. The World Health Organization recommends an omega-6/omega-3 ratio of 4:1 to 10:1.

### Fatty Acids Derived from Food Processing

Synthetic or unnatural types of fatty acids are also common components of Western diets and result from food processing. Fats are processed to increase their shelf life and to alter their physical properties. Monounsaturated and unsaturated fatty acids are chemically inert, whereas polyunsaturated fats are susceptible to oxidation. Polyunsaturated fatty acids degrade by oxidation and become rancid, thereby spoiling foods that contain these compounds. Therefore, products containing polyunsaturated fatty acids tend to have a reduced shelf life, but can be stabilized by converting the polyunsaturated fatty acids contained within these products to more stable monounsaturated and saturated fatty acids through the process of chemical hydrogenation. This process converts carbon-carbon double bonds to single bonds (Reaction 1):

### FAT AND HEART DISEASE

Risk for heart disease results from excess fat consumption and the type of fat that is present in the diet. Diets high in saturated fatty acids, especially those found in animal fat, increase the concentration of low-density lipoprotein (LDL) cholesterol or "bad" cholesterol. Elevations in serum LDL concentrations increase risk for arteriosclerosis. Consumption of *trans*-fatty acids, although only representing between 2 and 4 percent of calories in Western diets, also increases risk for heart disease, but the pathogenic mechanisms are not certain. *Trans*-fatty acids may be as efficient as natural saturated fat in increasing serum LDL concentrations, and their consumption replaces foods that contain beneficial unsaturated fatty acids. Consumption of omega-3 and omega-6 fatty acids, especially when they replace consumption of saturated fat, decreases risk for heart disease, in part by lowering LDL cholesterol levels. Omega-3 fatty acids are more protective than omega-6 fatty acids. Omega-6 fatty acids may lower serum HDL cholesterol, which is harmful because HDL protects the heart from disease. Omega-3 fatty acids may prevent heart disease by improving immune function, lowering blood pressure, and inhibiting the growth of plaques on blood vessel walls. Omega-3 fatty acids obtained from whole food sources such as fatty fish seems to be more beneficial than dietary supplements.

This process not only stabilizes food, but also changes its physical properties. For example, margarine is produced by the chemical hydrogenation of vegetable oils. This process produces a product that is more stable and solid than vegetable oil and mimics the consistency of natural butter. However, chemical hydrogenation of polyunsaturated fatty acids also results in the formation of "unnatural" *trans*-fatty acids, which are normally found only in trace quantities in foods from natural sources. *Trans*-fatty acids do not differ from natural fatty acids in their carbon chain length or degree of saturation, but differ in the orientation or stereochemistry of the carbon-carbon double bonds. Carbon-carbon double bonds can exist in both a *cis* (the hydrogen atoms that are attached to the carbon atoms that flank the double bond reside on a common plane) or *trans* (hydrogen atoms reside on different planes) conformation; this is a fundamental principle of organic stereochemistry. The double bonds present in fatty acids from natural, unprocessed food sources usually exist in the *cis* conformation (see Figure 1). *Trans*-fatty acids are abundant in foods that

undergo chemical hydrogenation and their consumption may increase risk for disease.

Nomenclature of Fatty Acids

All fatty acids can be identified by their “trivial” names, such as oleic or linoleic acid, but these names do not contain information that is necessary to infer their structure or physical properties, that is, the length of their carbon chains or the number and location of carbon–carbon double bonds. Therefore, a nomenclature system has been devised that describes the precise chemical structure of the molecule (see Table 1). The carbon atom that constitutes the carboxylic acid of the fatty acid is referred to as the *alpha carbon* and is designated as carbon number one; the methyl carbon that constitutes the other end of the molecule is referred to as the *omega carbon*. Fatty acids are named by the number of carbons in the chain and the number and location of carbon–carbon double bonds. For example, oleic acid is referred to as *cis*-9-octadecenoic acid, or 18:1(9); the 18 refers to the number of carbons in the fatty acid carbon chain, the 1 refers to the number of carbon–carbon double bonds, and the 9 in parentheses refers to the position of the double bond counting from the carboxylate carbon that is in the *cis* conformation.

*Fatty acids as membrane components and emulsifiers.* Fatty acids and triglycerols are lipid soluble and there-

fore are hydrophobic molecules that do not dissolve readily in water (as evidenced by the appearance of distinct oil and water layers in many oil-based salad dressings). In aqueous environments, fatty acids aggregate and form ordered structures. All life forms have taken advantage of the hydrophobic properties of fatty acids to make cell membranes, which are semipermeable barriers that separate cells from their environment. Membranes delineate the boundaries of the cell, enable cells to retain water, and form specialized internal structures called subcellular organelles that include mitochondria, Golgi apparatus, and lysosomes. Cell membranes are lipid bilayers that are primarily composed of lipid and membrane-bound proteins. Fatty acids present in cell membranes are components of phospholipids, and phosphoglycerides are the most abundant phospholipids in membranes. Phosphoglycerides are similar in structure to triglycerols. They contain two fatty acid molecules and one phosphate molecule esterified to a glycerol molecule. The phosphate molecule has a hydrophilic amino acid or sugar molecule attached to it. Phospholipids are amphipathic molecules because one end of the molecule contains a water-soluble phosphate molecule, and the other end contains a lipid-soluble carbon chain of the fatty acids. Therefore, phospholipids are ideal components of cell membranes because the phosphate end can dissolve in water while the fatty acid end interacts with other lipid molecules to form a barrier that restricts the efflux of water.

The amphipathic properties of phospholipids make them effective *emulsifiers*, which are chemicals that interact with both water and oils and prevent them from separating and forming two layers. Lecithin is a phospholipid that is synthesized by mammals and is found in high concentrations in eggs. It is also an effective emulsifier and a common food additive in margarine, salad dressings, chocolate, and a variety of baked items. Fatty acids are components of many household products including lubricants, cooking oils, soaps, and detergents.

TABLE 1

Classes of fatty acids		
Trivial name	Systematic name	Numerical symbol
<b>Saturated fatty acids</b>		
Lauric acid	Dodecanoic	12:0
Myristic acid	Tetradecanoic	14:0
Palmitic acid	Hexadecanoic	16:0
Stearic acid	Octadecanoic	18:0
<b>Monounsaturated fatty acids</b>		
Palmitoleic acid	<i>cis</i> -9-hexadecenoic	16:1(9)
Oleic acid	<i>cis</i> -9-octadecenoic	18:1(9)
<b>Polyunsaturated fatty acids (omega-6)</b>		
Linoleic acid	<i>cis,cis</i> -9,12-octadecadienoic	18:2(9,12)
Arachidonic acid	All <i>cis</i> -5,8,11,14-eicosatetraenoic	20:4(5,8,11,14)
<b>Polyunsaturated fatty acids (omega-3)</b>		
Linolenic acid	All <i>cis</i> -9-12-15-octadecatrienoic	18:3(9,12,15)
EPA	All <i>cis</i> -5,8,11,14,17-Eicosapentaenoic	20:5(5,8,11,14,17)
DHA	All <i>cis</i> -4,7,10,13,16,19-Docosahexaenoic	22:6(4,7,10,13,16,19)

Dietary and Biosynthetic Sources of Fat

Fatty acids found in mammals are derived from both dietary sources and intracellular biosynthesis. Humans can synthesize all of the necessary fatty acids with the exception of the essential fatty acids. Fatty acids are synthesized in most cells from excess dietary carbohydrate, amino acids, and from other fatty acids. Palmitic acid (16:0) is synthesized by mammals and is a precursor for the synthesis of all other nonessential fatty acids. The carbon chain of palmitic acid is extended by the sequential addition of two carbons to the carboxy terminal end of the molecule. This is an enzyme catalyzed reaction that uses acetyl coenzyme A (CoA) as a source of the two carbon atoms. Mono- and polyunsaturated fatty acids are synthesized by the desaturation of saturated fatty acids. The first double bond is formed between the C–9 and C–10 of palmitate or stearate to form palmitoleic or oleic acid. This is the first step in the synthesis of polyunsat-

urated fatty acids. This reaction is inhibited by dietary polyunsaturated fatty acids but activated by insulin and thyroid hormone.

Triglycerols are synthesized by most tissues from glycerol 3-phosphate, an intermediate in carbohydrate metabolism, and chemically activated fatty acids known as fatty acyl CoAs. This reaction occurs most frequently in the liver and white adipose tissue. In the liver, triacylglycerol synthesis is necessary for the assembly of lipoproteins, whereas triacylglycerol synthesis in adipose tissue functions to create long-term energy stores for mammals. Although a storage form of energy, fat is a dynamic tissue. Triacylglycerols constantly undergo hydrolysis and resynthesis in adipocytes. Newly synthesized triacylglycerol molecules remain intact for only a few days.

### Digestion and Transport

About 90 percent of dietary lipid is in the form of triacylglycerols, and typical adults consume about 60 to 150 g/day. During digestion, dietary lipids aggregate and form water-insoluble particles in the gut that must be disrupted before absorption. Specific enzymes in the stomach, called gastric lipases, and in the intestine, called pancreatic lipases, bind to the lipid droplets and catalyze the hydrolysis or removal of fatty acids from triacylglycerols resulting in the liberation of free fatty acids, diacylglycerols, and monoacylglycerols. Fatty acids are also liberated from phospholipids by pancreatic phospholipases. The products of triglycerol hydrolysis are made soluble by bile acids, which are negatively charged detergents that are synthesized from cholesterol in the liver and secreted into the duodenum. Bile acids form micelles, which are disc-shaped particles with a negatively charged exterior that is water soluble and a hydrophobic center that sequesters fatty acids. During digestion, liberated fatty acids are continuously transferred from lipid droplets to micelles. Virtually all free fatty acids are transported from the micelles into intestinal epithelial cells by passive diffusion. Lipids that cannot be made soluble are not absorbed and are excreted.

Once absorbed into the intestinal cells, short- and medium-chain fatty acids are released directly into blood and taken up by the liver. Long-chain fatty acids are resynthesized into triacylglycerols and complex with apolipoproteins to form lipid globules known as chylomicrons. Chylomicrons travel through the lymphatic system and then through the venous plasma. Most triacylglycerol in chylomicrons is metabolized by lipoprotein lipase that is bound to the surface of adipose and muscle cells.

### Metabolism of Fat

Most fat cells are derived in infancy and adolescence except in instances of severe childhood obesity. As fat stores accumulate, adipocytes increase in size but generally not

in number. Normal fat stores provide sufficient energy to sustain humans for several weeks during total starvation. During fasting, fatty acids are catabolized or broken down to acetyl-CoA, which is an intermediate in the citric acid cycle. This reaction requires carnitine, a derivative of the amino acid lysine. The oxidative breakdown of fatty acids occurs in mitochondria through a series of reactions known as beta-oxidation. Fatty acids are rich sources of energy; 44 moles of ATP are generated by the complete oxidation of 1 mole of a six-carbon fatty acid, whereas only 38 moles of ATP are generated from 1 mole of glucose, a six-carbon sugar. During starvation, acetyl-CoA can be converted to ketone bodies, which include acetone, acetoacetate and alpha-hydroxybutyrate. These compounds are produced exclusively in the liver but readily enter the circulatory system by passive diffusion. The odor associated with the generation of these ketones becomes apparent in the breath and urine of individuals. Ketone bodies are an alternative energy source for glucose during starvation, and are utilized by the brain and other tissues. Normally, ketones are rapidly metabolized by the peripheral tissues and do not accumulate in blood. However, if the citric acid cycle is depressed by low glucose due to starvation, diabetes mellitus, or a high-fat, low-carbohydrate diet, ketones accumulate in serum and a state of ketosis can result. High concentrations of ketones in blood can lower its pH and result in metabolic acidosis, which can be fatal during diabetic ketosis.

### Fatty Acid Regulation of Gene Expression

Polyunsaturated fatty acids and eicosanoids are informational or signaling molecules that can influence the expression of certain genes involved in lipid synthesis, breakdown, and transport. Omega-3 and omega-6 polyunsaturated fatty acids lower the accumulation of triacylglycerol in muscle by inhibiting triacylglycerol synthesis in the liver and accelerating the breakdown of fatty acids in the liver and skeletal muscle. Linoleic and linolenic acid, as well as certain pharmaceuticals, bind to and activate the transcriptional activity of a family of related nuclear receptors known as the peroxisome proliferator-activator receptors (PPARs). These receptors are transcription factors that can directly bind DNA and elevate the transcription of genes. The target genes are involved in the metabolism, storage, and transport of lipids, triacylglycerol, and fatty acids. These receptors also regulate the differentiation of immature adipocytes into mature fat cells.

Individual members of the PPAR family have different functions. In the fasting liver, PPAR-alpha activates genes that encode enzymes that metabolize lipids to ketone bodies and decreases expression of genes involved in fatty acid synthesis. As fatty acids are hydrolyzed from triacylglyceride, PPAR-alpha is further activated. PPAR-alpha activates the expression of genes in fat cells that are necessary for fatty acid uptake, triacylglycerol synthesis, and fat storage.

## PHARMACEUTICALS THAT TARGET FAT METABOLISM

Many of the most prevalent diseases in Western cultures are related to excessive caloric intake and sedentary lifestyles, diseases that include obesity, hyperlipidemia, diabetes, and arteriosclerosis. These states often occur in combination, and are diagnosed as syndrome x. Pharmaceutical have been developed to manage these disorders. These agents either inhibit intestinal fat absorption or affect fat metabolism by manipulating the activity of PPARs.

Fibrates (gemfibrozil, bezafibrate, fenofibrate) are pharmaceuticals that target and inhibit the function of PPAR- $\alpha$ . Thiazolidinediones target PPAR- $\alpha$ . Fibrates are effective in the treatment of cardiovascular disease. They function to elevate HDL levels by increasing the expression of proteins necessary for its structure, and decreasing plasma triglyceride by accelerating fatty acid oxidation in the liver. TZDs are effective in the treatment of Type 2 diabetes because they have a hypolipidemic and hypoglycemic effect.

Nondigestible commercial lipids have also been developed to limit total fat intake. One product, Olestra, contains fatty acids linked to the sugar sucrose. These products replace natural fat in foods, and were designed to taste like natural fat. However, they cannot be hydrolyzed in the gut and therefore are not absorbed. Other pharmaceuticals target and inhibit pancreatic lipase, such that natural dietary lipids are not broken down to fatty acids and therefore are not absorbed.

## Determinants of Total Body Fat

Fat is a storage form of energy, and as such only accumulates when energy intake exceeds energy output. Total body fat accumulation is determined by complex interactions among genes, environment, and behavior. The human body can adjust to a wide range of fat intake, but both deficiency and excess are associated with disease. In a normal, healthy individual, fat stores constitute 12 to 18 percent of total body weight in males and 18 to 24 percent in females. Excessive consumption of high-calorie foods and/or a lack of exercise elevate fat stores. In some cases, the genetic background alone can determine total body fat in the absence of strict dietary control. Children with obese parents are at higher risk of becoming obese, and studies of identical twins also indicate that risk for obesity has a strong hereditary component. Furthermore, more than 75 percent of the Pima

Indians are obese, again indicating a strong influence of genetics on fat accumulation. Many genes have been identified that control weight gain. The products of these genes regulate energy balance and expenditure and are signaling hormones that regulate appetite and fat metabolism. Some studies indicate that genetic factors, and the metabolic signals they generate, balance energy expenditure and appetite to form an individual's "set point" that specifies body weight. These signals include the satiety hormones such as serotonin and leptin. The neurotransmitter serotonin is responsible for "cravings" that can increase consumption of particular food types. Leptin is a peptide hormone that is secreted by fat cells and signals the hypothalamus. Leptin secretion is proportional to fat cell size, and increased leptin concentrations in blood signal the brain to increase energy expenditure and decrease food intake. Mice lacking the leptin gene or the leptin receptor become obese. Human mutations in the leptin gene are rare but result in obesity.

## Dietary Fat and Disease Risk

Lipids constitute about 33 percent of total energy intake in the typical North American diet, whereas Japanese diets have a lower fat intake (11 percent of energy from fat). Western-style diets are deficient in omega-3 fatty acids and contain excess omega-6 fatty acids. Some evidence indicates that prehistoric diets that were consumed through much of human evolution contained an omega-6/omega-3 fatty acid ratio that was near 1.0, whereas this ratio is about 20 in the typical Western diet. Vegetarian diets also tend to contain excess omega-6 fatty acids. Diets deficient in omega-3 fatty acids or diets that contain an elevated omega-6/omega-3 ratio may increase risk for cardiovascular disease and cancer.

Research over the past few decades has indicated that excess consumption of saturated fat increases risk for disease including heart disease (arteriosclerosis), obesity, diabetes, and certain cancers (see "Fat and Heart Disease"). Obesity is a clinical condition defined as having a body weight that is greater than 20 percent above a desirable body weight standard or a body mass index that exceeds 30 kg/m<sup>2</sup>. Obesity occurs in epidemic proportions in the United States and other Western societies, especially in individuals from lower socioeconomic level. Its prevalence is rapidly increasing in developing societies that are adapting Western lifestyles. The combination of increased fat intake and sedentary lifestyle (otherwise referred to as excess energy intake) increases risk for overweight and obesity. Increased body fat, in turn, is an independent risk for heart disease, diabetes, and high blood pressure. Elevated fat intake can also increase risk for cancers of the colon, prostate, and breast. The incidence of cancers of the breast is high in populations with high intakes of either natural saturated fat or *trans*-fatty acids, but not diets rich in olive oil, which contains high levels of monounsaturated fatty acids. High polyunsaturated fat intake in the form of linoleic acid (omega-6) in-

creases risk for breast cancer incidence in mice, compared to diets high in omega-3 fatty acids.

Cultures in which traditional foods have high concentrations of monounsaturated fats, products that include olive oil and fish, have lower incidence of heart disease compared to the United States. The prevalence of heart disease in Mediterranean countries is only 50 percent of that found in the United States, even when fat represents almost 40 percent of total energy intake. However, the decreased rates of heart diseases in these countries also reflects other dietary patterns including a high consumption of fresh fruits and vegetables and other lifestyle differences.

**FAUCHON, AUGUSTE FÉLIX.** Auguste Félix Fauchon (1856–1939) was a Parisian grocer who founded Fauchon, the luxury food store in the Place de la Madeleine in the 8th Arrondissement in Paris. Fauchon, who was born in Calvados, left school and moved to Paris, where he bought a wagon to peddle fruit and vegetables outside La Madeleine. In 1886, he bought a small shop across from the church, where he began to specialize in high-quality foods including charcuterie, cheeses, poultry, confectionery, and wines, as well as produce.

Fauchon became more and more popular among the rich and fashionable of Paris along with its reputation for quality, luxury, and exclusivity. During Fauchon's lifetime, his shop sold only French products; importing exotic items from outside France remained the domain of the neighboring grocery owned by Fauchon's friend Ferdinand Hédiard.

Between the two world wars, Fauchon expanded his operation to include a catering service, a tea and pastry salon, and a food laboratory to prepare products such as confits and bottled fruit. After his death, the company added specialty items from around the world and continued to develop its own luxury products, including teas, honeys, jams, spices, pâtés, chocolates, and pastries.

Today, Fauchon includes several departments, including the tea salon, wine cellar, pâtisserie, charcuterie, produce shop, and épicerie for Fauchon-brand products, including teas, coffees, and spices.

**FAVRE, JOSEPH.** For the first half of his career, Joseph Favre (1849–1903) followed the traditional path of a chef. He was apprenticed as a teenager in his native Swiss canton of Valais, and thereafter moved around Europe serving in aristocratic households, grand hotels, and restaurants in Switzerland, Germany, England, Italy, and France. In Paris he was also employed by the fashionable caterer Chevet, whose shop was located in the Palais Royal.

Once he had received recognition as a chef, Favre turned his attention to promoting the welfare and status of cooks, founding a professional society and a trade journal. He also wanted to bring the best of French cuisine to the masses, a view which put him at odds with some of his fellow chefs.

Favre wrote prolifically on all sorts of culinary topics, and in 1894 his articles were gathered together into the four-volume *Dictionnaire universel de cuisine: Encyclopédie illustrée d'hygiène alimentaire* (The universal dictionary of cuisine: illustrated encyclopedia of food health). The *Dictionnaire* contained thousands of recipes, menus, profiles of well-known people in the field (including Favre himself), and a history of cooking that was pronounced "very interesting" in Prosper Montagné's *Larousse gastronomique*. Today, manufacturers of traditional foods included in the *Dictionnaire* continue to use the mention by Favre as an endorsement for their products.

**FEASTS, FESTIVALS, AND FASTS.** A feast is commonly thought of as a lavish meal; in a religious sense, it is also a day of commemoration set aside for an important personage, such as a saint. The word “feast” also connotes sensual delight, often excessive, as in the expression “a feast for the eyes.”

A festival is a period of celebration, often centered around a religious feast day or a holiday, such as Christmas, a period of holidays celebrating an event (such as the completion of harvest), or a season (e.g., a winter carnival). Also, a festival can mean an unusually intensive or exaggerated series of presentations, such as a film festival. Finally, a fast (when used as a noun) marks a period of abstinence, such as the Lenten fast for Christians or the Ramadan fast for Muslims.

The concepts of feast, festival, and fast are closely interconnected. A feast day, such as St. Patrick's Day, for instance, is often the center of prolonged festivities. In such cases, the religious rituals such as attending church and, perhaps, fasting, are components of a larger festival event that frequently includes feasting, in the sense of excessive eating or drinking.

### Food and Festival

Food is a major component of festival. Often it is part of a ritualized exchange, as when Halloween trick-or-treaters are given candy or are invited in for doughnuts and cider, or when Christmas carolers are rewarded with cookies. Food is often present in a formal, sacred meal. For instance, the Roman Catholic mass centers around the sacrament of the Eucharist, the transubstantiation and eating of bread and wine as the body and blood of Christ. While individual communicants each partake of only small amounts of the host, the Eucharist is invariably described by Catholics and Orthodox Christians as a (sacred) meal. The ritual most probably derives from the celebration of the Jewish Passover, which is celebrated with the sacred meal known as the Seder. The Seder is generally celebrated in the home, but is no less sacred or ritualized for that fact. Traditionally, during the meal four questions are asked by the youngest male child present, and certain foods are present on the table, each with specific symbolic value. Wine is consumed on four occasions during the meal, and the proceedings can take on a very festive demeanor, but the Passover Seder is a religious, historical, and sacred feast. Conversely, Jews

fast from sundown to sundown on the high holy day of Yom Kippur.

The American Thanksgiving holiday is also centered on a meal, a feast that is likewise symbolic, ceremonial, and formalized, but not specifically belonging to any particular religion or denomination. However, the occasion is frequently used to express religious sentiments. The Thanksgiving feast commemorates an early harvest celebration held among English Puritan settlers in Massachusetts and their Native American benefactors. The tradition became an officially proclaimed national holiday under President Abraham Lincoln, in 1863, during the Civil War. As such, Thanksgiving has always had a strong element of patriotism and nationalism associated with it. While not a religious celebration in any strict sense, Thanksgiving can still be said to be a sacred event, in the sense of a secular ritual, one with strong political overtones (Moore and Myerhoff, 1977).

The events above are all more than simply meals. They are highly elaborated performances done with reference to religious and political worldviews, and are usually carried out by a group. One can examine the role of food in other celebratory events along these axes of formal-informal, and sacred-secular, such as Emancipation Day picnics or house-warming potlucks. For instance, in the United States people frequently gather at a home to watch the Super Bowl, the championship game of the National Football League. This televised sporting event has been promoted as an unofficial American holiday, and it is said to be played on “Super Bowl Sunday.” Since people gather together, food is served on these occasions, but generally there is no formal, sit-down meal. Frequently, it is a potluck, with the hosts providing a large and plentiful central dish such as chili or spaghetti. Very often, the food consists of store-bought goods such as submarine sandwiches, or pizza, and beer. Thus, the food served at the Super Bowl Sunday party is itself mediated—it is bought in supermarkets or ordered by telephone—as the game itself is mediated.

Michael Dietler (2001) defines “feast” as any meal marked as different from everyday domestic meals, or from the exchange of food without consumption. He emphasizes that it is a kind of ritual activity. Likewise, the concept of “fast” depends on a ritual context in order to distinguish the abstinence from food from a diet or an eating disorder. Idiosyncratic fasting is often done to signify devotion to a saint or deity, for instance, or to a cause, as when individuals go on hunger strikes to protest certain situations. Idiosyncratic fasting often becomes a badge of marginality. In this latter regard, Caroline Walker Bynum points out that in Europe in the Middle Ages it was far more common for religious Christian women to use the denial of food as a sign of sacrifice and devotion than it was for men, and she suggests that many of what are regarded as eating disorders in the present time are also overwhelmingly a female problem. That is,

many aspects of feasts and fasts are gendered, including food preparation, consumption, cleanup, and disposal.

For the denial of food to be considered a “fast,” both the faster and the scholar consider the denial of food and/or drink as occurring in response to a sacred calendar that proscribes the consumption of certain foods during certain ritual periods or holy days; or the individual decides to fast in order to fulfill a vow of some sort, to purify oneself, or to show intense devotion to a deity. Feast and fast represent the overrating and underrating of food, respectively—food as plenty and food as denial.

Feast and fast meet in the Islamic holy month of Ramadan. Muslims do not eat between sunrise and sunset, but break the fast every evening with a festive meal. Neighbors and friends routinely visit during these evening events, which feature special desserts to mark the occasion. The end of Ramadan is celebrated with the festival of Eid. With Ramadan a ritualized relationship, a rhythm, of feast, fast, and festival may be observed—periods of fast interspersed with periods of feasts. Each takes increased meaning from its juxtaposition to the other. Eid, as a celebration, is especially meaningful coming at the end of a holy month of fast and reflection, much as Mardi Gras and carnival precede the forty days of Lent in Christendom. Very generally, it is often thought that feasts usually occur during periods of plenty, particularly after a harvest is completed. Surplus is consumed in celebration, as well as stored against the winter, famine, or other periods of want. Indeed, many celebratory feasting events mark both the pastoral and the agricultural cycles: ox slaughtering, grape harvests, apple butter festivals. However, as cultural events, both feasts and fasts are more complicated than this.

How, for instance, might the various proscriptions against the eating of certain foods in various religions be explained? Mary Douglas has produced the best analysis of the Jewish dietary laws in her book *Purity and Danger* (1970). She argues against the standard interpretations of the taboos involved in keeping kosher, that the foods involved such as pork were likely to be unhealthy due to poor means of preservation available in the biblical period. Such an explanation, she points out, does not explain the continued existence of these laws. In her analysis, she demonstrates that each of the animals listed as “abominations” in the biblical Book of Leviticus are creatures that possess characteristics of other species, who therefore blur the boundaries and cultural categories, and that are therefore considered taboo. “The unclear is the unclean,” she concludes. While this interpretation may or may not be universally valid, it does show the complexities of culture that are inherent in food, eating, and ideas of the edible (Long, 2000).

Holiday eating is a ubiquitous form of feasting, often with foods that are themselves symbolic. Many religious feast days are also secular holidays, such as Christmas; or, at least, many popular holidays have religious underpin-

The *Ngusaba* or Volcano Festival celebrated by twenty-eight Hindu villages near the Gunung Agung Volcano at Duda, Bali (Indonesia). © ROGER RESSMEYER/CORBIS.

nings to them. Some, such as St. Patrick’s Day or Valentine’s Day, are not governmentally recognized holidays. No days off from work or school are granted. Still, they are celebrated traditionally by large numbers of people. Likewise, Halloween is the Eve of All Hallows, or All Saints’ Day, in the Roman Catholic Church. Most traditional holiday and celebratory occasions, including religious and ethnic events such as Hanukkah, or Passover, are marked with special foods. The American Thanksgiving typifies the feast as experienced by many people today. The celebration of Thanksgiving is traced to a harvest feast in Plymouth, Massachusetts, in 1621, even though there were many other religious services of thanksgiving, usually involving fasts rather than feasts, that preceded the Plymouth event in the New World. Many Native Americans today regard the occasion as a national day of mourning, since the indigenous peoples were thanked for their assistance to the early colonists by later policies of betrayal and genocide.

Nevertheless, Thanksgiving is thought by many to be an inclusive celebration. For the occasion, the foods are prepared not only to be consumed, but also to be displayed. They are appreciated for their appearance and for their abundance. The table setting is important—special china and silverware, rich in family history, may be brought out. The dishes and the foods are arranged aesthetically, with the turkey being the centerpiece (Long, 2000).

Many aspects of personal and social identity are displayed along with the foods. For instance, family relationships are indexed by the favorite dish prepared by members of the extended family—a cousin’s stuffing or a grown sibling’s apple nut cake. Ethnicity, too, may be present in the form of additional dishes such as lasagna. There are even vegetarian organizations that have a meatless Thanksgiving with a live turkey present. Likewise, regional background is manifested in the foods and the ways they are prepared (Long, 2000).

### Ritual Feasts and Ritual Fasts

Feasting done in ritual contexts or as rituals themselves (again, the Passover Seder, e.g., or even the Sunday dinner) is usually in some way festive. Even foods served during mortuary rituals (the eating and drinking during the Irish wake; the cold cuts served after a funeral) serve this socially integrative, generally light-hearted function. Fasts are thought to be “fasts,” rather than “diets” or “eating disorders,” precisely because they are carried out in reference to a sacred overarching symbolic system, usually religious, but sometimes political.

Ritual, festival, and celebration have in one form or another long been a source of great interest to folklorists and anthropologists. In fact, anthropology had its beginning in (the now largely repudiated) theories of Sir James George Frazer (originally published in 1911) concerning religion, belief, magic, and ritual, as well as the related work on belief by Edward Tyler from 1873. In 1925 Bronislaw Malinowski revolutionized the practice of anthropology in the twentieth century with his field studies of ritual, along with religious and magical beliefs and customs. The list can go on, but any such list will include the work of the French folklorist and sociologist Arnold van Gennep who, in the first decades of the twentieth century, provided systematic analysis of life cycle and calendrical rites of passage, and the later work of Victor Turner in the 1960s through 1980s. Both these scholars produced analyses and vocabularies that have become paradigmatic, not only in anthropology but in other disciplines as well. Scholars are widely familiar with Tur-

ner's ideas concerning *communitas* and liminality that, along with his phrase “betwixt and between,” are regularly used to this day not only by anthropologists but also folklorists, ethnomusicologists, historians, and indeed anyone working with ritual materials. Van Gennep's term “rites of passage” has become part of everyday speech. Along with Mary Douglas, Turner put the study of symbols and symbolic action at the top of the research agenda for the second half of the twentieth century.

With the rise of cultural studies critiques that have engaged questions of politics, race, social class, gender, and power, newer approaches to the study of ritual have arisen that complement rather than entirely supplant the symbolic analyses inspired by Turner. After Stanley Tambiah's article “A Performative Approach to Ritual” was published in 1985, along with Turner's own growing interest in performance, a great many important recent studies of what folklorist Beverly Stoejtje (1993) calls “the ritual genres” came out of performance studies—a field influenced by Turner's work but also by more recent perspectives on feminism, postmodernism, and cultural studies, as well as earlier movements in rhetoric and theater.

At the same time, the emphasis on performance and performativity has led to an expansion of the materials of ritual studies. Felicia Hughes-Freeland says, “The focus on performance allows us to understand situations interactively, not in terms of communication models, but in terms of participatory ones” (p. 15). Parades, protests,

and street theater generally are increasingly being referred to and studied as ritual or at the least as ritualized behavior, with the work of folklorist Susan G. Davis being particularly influential. Further, such events are compared and contrasted in other works to performances such as Jacobean theater or the mass media. National ceremonies, nationalizing events, and beauty pageants all take their place in the literature on ritual. In fact, people find the kinds of meanings scholars refer to under the rubric of “ritual” in a wide range of events and activities; that is, people invest certain actions with symbolic meaning or transformative power. That is ritualization, and it is up to the researcher to determine how people create this kind of dynamic. Likewise, feasting is emerging as a critical site for investigation within archeology, anthropology, and folklore. Foodways or food studies is a growing subfield within these disciplines, and is an important component of the study of ritual, festival, and celebration, as seen in works by Caroline Walker Bynum (1987), and Michael Dietler and Brian Hayden (2001).

The present author argues that ritual is not necessarily in opposition to festival (i.e., one confirms; the other subverts) but simply that ritual is a discrete form, distinctive from festival and celebration but frequently a component of these, much as game, sport, music, dance, food, story, and so on, are each discrete genres but also available as constitutive components of festival. Because festival and ritual are closely intertwined, because both often mark transitional points in the life cycle or recurrent, transitional, or important points in the year, festival is thought of as ritualistic. As has been seen, marking, commemorating, or celebrating something is not the same as causing it. However, these two features—celebration and performativity—are both capable of being potentiated in ritual, as well as in other genres such as festival and demonstration. It is not the scope of an event that makes it ritual. One may light a candle simply because one likes candlelight, or to ward off insects in the summer, and not think of these activities as special. However, lighting a candle at Christmas, even decoratively, is done because of the sense that it is a special time (another frame) and therefore may be felt to be ritualistic, despite the informality and secularity of the act. These continua—formal-informal, religious-secular—are self-evident. One may light Advent candles in the home before Christmas, a more formal and more religiously oriented activity, but not as formal or religious as the lighting of candles in church for Sunday or Christmas services.

Ritual, festival, celebration, holidays, public display events—what links these terms analytically is the combination of their performative and celebratory aspects, and the fact that rites of public display, like ritual, are performative. Food presentation and consumption—and the lack of it—are used to mark social time and establish social identity. Feasts precede and follow days or weeks of fast; they mark and celebrate periods of plenty after sea-

sonal harvests or animal slaughterings. Fasts also indicate special days of the week, month, or year; may be used as part of life-cycle rituals such as coming-of-age; and are used by individuals to communicate being in a special state—denial as devotion to a deity or a cause (e.g., the Irish hunger strikers) or penance and suffering as a means to purification.

**FERMENTATION.** Fermentation is one of the oldest known food preservation techniques. Along with drying and salting, fermentation was a key method of extending the life of foods, allowing them to be available, and eaten safely, in times of scarcity or seasonal non-availability. These methods helped allow the transition from hunting and gathering to organized food cultivation and storage, which took place some ten to fifteen thousand years ago in the Middle East.

Fermentation involves the action of desirable microorganisms, or their enzymes, on food ingredients to make biochemical changes, which cause significant modification to the food. Often lactic-acid bacteria convert the carbohydrate energy source of food, such as lactose in milk, to lactic acid; examples are yogurt and cheeses from milk, and pickles from fruits and vegetables. Alternatively, yeasts, often of the *Saccharomyces* species, may convert the glucose to ethanol and carbon dioxide in leavened breads, or the sugars in grain or fruit beverages to beers and wines. Molds also can be active in certain fermentations, such as Stilton cheese and soy sauce. It is estimated that about one-third of all the food we consume is fermented. World estimates for beer consumption are about 22 million gallons, and a total of 15 million tons of some one thousand varieties of cheese are eaten annually.

### Fermented Beverages and Foods

Fermentation is often the key to the safe, enjoyable consumption of perishable food materials, as it changes their composition, flavor, and texture. For example, milk is a nutritious but highly perishable beverage. Originally, in the Middle East, milk carried in animal-skin containers, often on horseback, would sour naturally, to produce acidic fermented milk. The combined action of the two lactic-acid bacteria, *Streptococcus lactis*, producing lactic acid, and *Lactobacillus bulgaricus*, producing lactic acid and acetaldehyde, a major contributor to flavor, are involved in yogurt production. The Tartars of Central Asia used the milk of horses, donkeys, or camels to produce a fizzy, gray acidic and alcoholic drink, *kumiss*, in which yeasts were active.

In acid conditions, the milk protein, casein, denatures and is precipitated to form a curd, producing cot-

Sugar products are shown fermenting in an open tank at a rum distillery in Guadeloupe. © REINHARD EISELE/CORBIS.

tage and soft cheese. By stirring and pressing, whey is removed and a more solid curd is produced, which by ripening or maturation produces semi-hard or hard cheeses. Surface-active bacteria of *Brevibacterium linens* are active in producing the aroma of Limburger type cheeses, while the blue molds of the genus *Penicillium* give Stilton and Gorgonzola cheeses their character.

The use of *Saccharomyces* yeasts has allowed the production of a range of fermented beverages, enabling safe consumption of liquid when fresh water supplies are not available. Lagers, the light golden, gassy beverage made by “bottom” yeast fermentation of cereal extracts, were first made in the regions of Germany and Czechoslovakia, but are now produced and consumed throughout the world. In Africa, a thick, sour alcoholic beverage is made from sorghum or millet, or sometimes maize or banana. These sorghum beers are important sources of nutrients, particularly B vitamins, to people on marginal diets in these regions. The Romans planted extensive vineyards in North Africa to harvest and ferment their grapes into wine, thereby producing a fermented beverage that could be readily stored, transported, and consumed when and where required.

Distillation of these alcoholic beverages, such as whiskey from beers, brandies from grape wines, or arrack from palm or rice wine, further extend our range of drinks and play important cultural roles in festivities.

### Fermentation Vessels and Starter Cultures

Art meets science in the production of fermented foods. Traditional practices are passed down through generations of producers, often small in scale, and consumption patterns often have great cultural importance. In Scandinavia, traditionally the brides and mothers jealously

guard their own supplies of sourdough starters, so that they can always make the desired bread for their partners and families. In West Africa, a homeowner keeps a supply of *dawadawa*, a dried fermented African locust bean paste (*Parkia* species); it is used to give everyday soups and stews the desired “meaty” flavor, while also providing important nutrients, such as riboflavin, the B vitamin that protects against blindness, which is endemic to the region due to nutritional deficiency.

In Korea, few meals are complete without *kimchi*, a pickled fermented cabbage, which may also contain fish and other components. The practice of every home having their own *kimchi* jars, often on their verandahs, originated as a way of preserving vegetables through the cold winter season, providing year-round vitamin C. *Kimchi* together with *kochujang*, the fermented red pepper paste, give Korean preparations a unique and characteristic attractive color and flavor.

Where food fermentation occurred naturally as conditions favored particular organisms, an important art arose to encourage the desired fermentation organisms, while preventing undesirable microorganisms from developing, for successful fermented food production.

Food storage often took place in earthenware vessels, whose semipermeable inner walls were difficult to clean completely. This allowed a biofilm of desirable microorganisms to remain, to initiate a successful fermentation of the next batch of food. Because of their significance, the vessels themselves were artistically designed and treasured. Interesting examples can be seen in museum collections, such as the Nezu Museum in Tokyo, Japan, and a museum dedicated to *kimchi* in Seoul, South Korea.

In Europe, the fermented meat producers, while using ceramic or metallic vats with smoother, more easily cleaned surfaces, developed the technique of “back-slopping” to introduce a small quantity of the fermenting liquor from the previous batch of meat to initiate successful fermentation.

In many cases, dried grains or balls of the derived fermenting microorganisms on cereal or other substrates would be used to start fermentation. Baker’s yeast may be used in this work. Kefir grains are used in North Africa, the Middle East, and Russia for production of kefir, *laban*, or *leben* fermented milks. *Ragi* is used in Indonesia and throughout East and Southeast Asia as *inoculum* for *lao-chao* and other fermented foods.

### Cultural Diversity

The production, consumption, and enjoyment of different fermented foods reflects the diversity of cultures and cuisines that make up our varied world. In Chinese and Japanese cuisines, *shoyu*, or soy sauce, is added almost universally to dishes, while the Indian vegetarian diet depends on fermented cereals and legumes, often in combinations, as in *dosas* and *vadas*. The art and science of fermenting meat to a wide range of salamis are vital to the enjoyment

of Eastern and Central Europeans, while Italian food market stall holders proudly display their mold-covered fermented sausages and traditional cheeses.

As people migrate, they normally carry their traditional fermented food practices with them. The range of fermented cheeses and meats in Latin America reflects the European origins of these populations, and the wineries of Chile were originally established by French families. Consumers of imported wine, chocolate, coffee, or tea are all beneficiaries of the internationalism and significance of fermented foods.

### FERMENTED BEVERAGES OTHER THAN WINE AND BEER.

Fermented beverages have been produced and consumed all over the world and over a very long time span. Man discovered that sugar solutions of different origins, if left standing rather warm, will start fermenting spontaneously into an alcoholic beverage that also often contains lactic acid. The requisite microorganisms, *Saccaromyces* yeasts and *Lactobacillus* bacteria, are abundant almost everywhere and will do their duty, producing alcohol and lactic acid. A similar fermentation process of animal and vegetable foods is the lactic-acid fermentation that yields, for instance, sour herring in Sweden, and sauerkraut.

Fermented beverages can be divided into two groups, wines and beers, broadly defined. Wines are fermented from various fruit juices containing fermentable sugars. Beers come from starch-containing products, which undergo enzymatic splitting by diastase, malting, and mashing, before the fermentable sugars become available for the yeasts and bacteria. The enzymatic splitting of the starch can also be performed either by human saliva, containing amylases, or by molds. Narrowly defined, beer is barley beer and wine is grape wine.

Detailed information on fermented beverages all over the world can be found in Hardwick and colleagues (1995, 63–68), Steinkraus (1979), Arnold (1911), and Campbell-Platt (1987).

### Beer from Cereals

*Bouza* is produced in Egypt and is probably the forerunner of beer in Ancient Egypt. It is prepared from malt of

Old cider press at Happy Land near Ashton Keynes, England, 1934. Two hundred sacks of apples were pressed daily to make cider during the harvest season. English cider is fermented while Americans generally drink the unfermented juice, either raw or pasteurized. © HULTON-DEUTSCH COLLECTION/CORBIS.

milo (a grain sorghum that resembles millet) and crushed baked loaves of bread. Residue from an earlier fermentation is used as a starter and both lactic-acid bacteria and *Saccaromyces* are involved in the fermentation process to get this sour alcoholic beverage. *Talla* from Ethiopia is a very similar to *bouza* and can be produced from barley and wheat. The bread loaves are heated to give a roasted character, and the pots are fueled by olive wood to give a smoky taste. *Talla* can also be spiced with hop leaves and stems, and spices.

**Wheat beer.** Wheat beer—and rye and oat beer as well—are frequently made from mixtures of malt and the crushed grains of these cereals with barley. Often the beer is bottled with the yeasts for continued fermentation in the bottle. Wheat beer—which is top-fermented and thus, technically, an ale—is particularly popular in Bavaria and in Belgium and northern Germany, in varieties such as *lambic*, *Gueuze*, Wit beer, Trappist beer, and *Berliner Weisse*.

**Rye beer.** Rye beers such as *kalja* and *sabti* in Finland, similar beverages in the Baltic area, and *kvas* (“kvass” in English) in Russia are produced in northern and eastern Europe, where cultivation of rye is widespread. *Kvas* has been the basic beverage for the Russian people for centuries. Its importance is indicated by many proverbs such as “Eat cabbage soup with meat, but if you don’t have it, eat bread and *kvas*.” The use of *kvas* is documented from about the year 800. Traditionally it is spontaneously fermented. In a broad sense, *kvas* is any sour and alcoholic fluid made from honey, bread, cereals, birch sap, fruits, beets, or cabbage. Red-beet *kvas* should always be used to produce *borshch* (“borscht,” in English—red-beet

soup). In a narrow sense, *kvas* (that is, bread-*kvas*) is produced from rye malt with or without other cereals or sour-fermented rye bread as adjuncts, and the beverage is spiced with peppermint. Most of the consumed *kvas* is of low alcohol content, only some few percent.

**Oat beer.** Oat beer is today mostly used as an adjunct in certain stouts called oat stouts. A stout is a dark ale, made of roasted malt, which occurs in several varieties such as sweet and dry (Guinness). Oats have also been used in traditional Norwegian beer production.

**Rice beer.** Another type of cereal beers is made from rice, and these have been produced in all the rice-growing areas of the world. The best-known example is sake from Japan, which has a documented history of more than two thousand years. The principal difference from the malting of barley lies in the *koji*-process of rice. *Koji* is a culture of *Aspergillus oryzae*, which grows on steamed rice, and saccharifies the rice starch (that is, converts it to sugar) and decomposes the rice proteins. The sugar produced in the sake mash is later fermented by the already-present *Saccaromyces cerevisiae*. The mash is acidified either by adding lactic acid to it or by facilitating the growth of lactic bacteria to form the seed mash, *moto*. Sake is a clear, pale-yellow liquid with an alcoholic content of about 15 percent and a characteristic estery (artificially fruity) aroma. It is slightly sweet and slightly acidic and has a high amino-acid content compared to wine and beer. Other similar beverages from rice are known from other eastern and southern Asian countries such as China, Thailand, India, Malaysia, and the Philippines.

Another similar fermentation process is performed by the inoculum *ragi*, present in Southeast Asia. *Ragi* contains the mold *Amylomyces rouxii*, the yeast *Endomycopsis burtonii*, and sometimes *Hansenula* yeasts; it produces a pleasant alcoholic and acid beverage from rice or cassava, called *tape ketan* in Malaysia.

**Sorghum and millet beer.** Sorghum beers, known as kafir beers in Africa, are made from malt from sorghum (*Sorghum bicolor*) or from the related grain, millet (*Pennisetum typhoides* and *Eleusine coracana*). Often-used adjuncts are maize (corn), malted or unmalted sorghum or millet, and malt amylase. Lactic acid is used as a flavoring and preserving agent, and the alcoholic fermentation is performed by *Saccaromyces*. Nowadays, these traditional African beers are not only produced in tribal areas; they are also available in home-brewed urban and industrially produced versions. They are opaque, rather thick pinkish-brown liquids with an estery (artificially fruity) or fruity odor, and a sweet and sour taste.

**Maize beer.** *Tesquino* and *zendecho* from Mexico and Latin America are made from malted maize and spontaneously fermented by *Saccaromyces cerevisiae*. These beverages might be as ancient as the oldest beers of the Old World, dating back about eight thousand years. Another beer is *chicha*, made by Andean and Central American In-

dians. The starchy material is chewed into dough, which is dried and later placed into warm water where the amylase action is finished. Then a starter (a small amount taken from a prior fermentation) is added, and the lactic-acid and alcoholic fermentation begins. Today much of the chicha is made using a maize malt rather than saliva.

### Beer from Starch Products

All kinds of starchy items, such as manioc (cassava), potatoes, beets, and various roots, are included in this group. To get fermentable sugars, the starch has to be split either by diastase in malt, by saliva, or by molds, as with rice. In South and Central America, almost all of the traditional beers were originally produced by chewing either the cereal maize or other starchy vegetables. One of the most popular has been the manioc, both the sweet and the bitter; sweet potatoes, mangabeira (*Hancornia speciosa*), cashew, Jaboticaba (*Myrciaria cauliflora*), pineapples, bananas, and algarroba pods have also been used. In the tropical forest tribes, the favorite manioc beer was prepared as follows:

The roots, cut into thick slices, were first boiled, then squeezed and partly chewed by young girls. The mass, impregnated with saliva, was mixed with water and heated again over the fire. The liquid was afterward poured into huge jars, half buried in the ground, covered with leaves, and left two to three days to ferment. A fire was built around the jars to warm the beverage before serving it. Each extended family manufactured its own liquor. When a bout was organized, drinkers went successively to each hut, exhausting the available supply. The women served the liquors in huge calabashes (Steward, vol. 3, 1948, p. 127).

An earlier popular American low-alcoholic beverage is root beer, which consists of an infusion of sarsaparilla, sassafras, spruce, wild cherry, spikenard, wintergreen, and ginger, with sugar and yeast. Today, it is a soft drink containing some of these ingredients at its best; otherwise, it is artificially spiced.

### Wine from Fruit and Vegetable Juices

**Fruit wine.** Fruit wines are produced with almost the same technique as grape wines. Specifically-named fruit wines such as cider (from apples) and perry (from pears) are produced, as well as wines from other fruits. The technical difference between these two groups is the alcohol content—5 to 7 percent in the first group and up to 18 percent in the second group—which depends on sugar addition.

**Tree-sap wine.** Saps from various trees have been used to produce alcoholic beverages; examples include maple sap (from *Acer saccharum*, the sugar maple) in North America, and birch sap (from *Betula pubescens*, the downy birch) in northern Europe. The manifestation of the symbiosis of yeast and bacteria cultures, which looks like a jellyfish, on the wounds of spring birches has been used in Europe as a folk medicine and is called “*Volga-swamp*.”

**Sugarcane wine.** Wine made from the sugarcane, *Saccharum officinarum*, together with molasses, is distilled into rum.

**Cactus-plant wines.** The tall perennial plants of the genus *Agave*, which grow in Mexico and nearby areas, give a sweet, slightly bitter sap, called *agua miel* (literally, honey water), which is fermented into pulque, either spontaneously or through the use of an inoculum from a previous fermentation. The Aztecs were familiar with the product. Pulque is an important food beverage for the poor in the semiarid areas of Mexico. If pulque made from *Agave tequilana* is distilled, the resultant liquor is called tequila; if pulque made from another agave is distilled, it is called mescal. Before the contacts with the European settlers, only a few American Indian tribes north of Mexico made alcoholic beverages. They were the Akimel O’odham (Pima), Tohono O’odham (Papago), and the River Yuman peoples in southern Arizona and northern Mexico, and they produced wine from the saguaro cactus as well as from the agave and the mesquite. In the East, the Cherokees made wine from persimmons. During an important ceremony in July, the Papagos and the Pimas drank enormous quantities of the wine to induce rainfall in their desert areas.

**Sugar-palm wine.** Some examples of wines made from palm sap are *surra* from *Borassus flabillifer*, *toddy* and *temba* from the coconut palm *Cocos nucifera* (from which arrack is obtained by distillation), *malovu* from *Elaeis guineensis*, a kind of undistilled “rum” from *Hyphaene coriaca* and *Hyphaene critina*, *Phonix reclinata*, *Raphia pedunculata*, and *Raobia vinifera*.

### “Wine” from Animal Sources

**Mead.** Honey is probably among the first foods gathered by *Homo sapiens* and its predecessors, and mead, the wine fermented from honey, may well be one of the oldest alcoholic beverages. Honey has also been much used as an adjunct to sweeten many kinds of beers over the centuries. Mead was the drink of the Nordic gods, whereas the people drank beer. The modern methods of production of mead are described by Andrej Jarczyk and W. Wzorek (1977).

**Fermented milk.** Only milk from human beings and horses has a relatively high concentration of milk sugar (lactose)—6.9 percent, in comparison with the 4.9 percent in cow’s milk—which makes it easier to ferment milk from mares than that from cows. People from central Asia (Tajikistan, Uzbekistan, and Kazakhstan) and Mongolia have fermented mare’s milk, making the alcoholic beverage *kumiss*, and it appears that milk from camels, sheep, yaks, and reindeer has been used similarly.

**FESTIVALS OF FOOD.** Food festivals can celebrate one particular ingredient, single dishes, or entire culinary cultures. Their public display, orgiastic consumption, or their playful way of dealing with food provide us with illustrations of the fundamental importance of such festivals for the development of culture.

### Prehistoric Roots

Alternating periods of malnutrition with certain occasions of extraordinary food consumption is typical for economies of penury. In the early phases of cultural development, therefore, the simple abundance of food was already reason enough for the celebration of a feast. Greenland's Eskimo communities, for instance, had spontaneous feasts whenever a large animal like a whale was captured. In order to hunt game and gather fruits in a world perceived as filled with spirits (animism), hunting and gathering societies depended on the help of shamanic rites. These rites were intended to persuade faunal and floral spirits to release animals and plants for human consumption. Game was always divided among the hunters and their community according to a customary ratio of distribution. This ancient practice gave rise to a variety of ideas and rituals. Sacrifice was one of the most prominent. There have been attempts to deduce the principle of gift giving and the exchange of gifts

Pig roast at Atuona, Hiva Oa, French Polynesia, in 1998. Pig roasts are popular adjuncts to all sorts of public feasting in the islands. © NIK WHEELER/CORBIS.

**FERTILE CRESCENT.** See *Mesopotamia, Ancient*.

from this primordial partitioning of food. Even though various disciplines have theorized and discussed the subject extensively, its original character has not developed clearly. The attempted explanations ranged from the sacrifice as an act of reciprocity to the sacrifice as a community at table, where gods and humans take part. Essential, however, was the fact that the food offered was consumed during the festive ceremony and only the inedible parts (bones, gall bladder) or minor pieces (fat) were offered to the higher beings. Bulk slaughtering, like that on the occasion of the “hekatomb” sacrifices in Greek antiquity, originally limited to the offering of one hundred head of cattle, became popular festivals with plenty of food for everyone.

Mass feeding in ancient societies certainly was an effective instrument for the manipulation of public opinion. In the case of Julius Caesar, it helped to create a dictatorship. He celebrated his victory over Gaul, Egypt, Pontus, and Africa in September 46 B.C.E. In order to outdo the triumphs of his predecessors, Caesar not only rewarded his soldiers, but almost the entire Roman citizenry. Approximately 320,000 people received a present of 100 denars and a special allocation of oil and grain. Meat also was distributed gratuitously and the Roman masses were entertained at 22,000 tables before viewing the games. The obligatory social mechanism behind this phenomenon was first described by Marcel Mauss as “potlatch” in his fundamental study on the “gift.” Individuals who are offered a gift are obliged to reciprocate. This system, widely operating in traditional societies, could be seen in two different forms: the potlatch of gifts and the potlatch of destruction. Only the wealthy were capable of leadership because they could oblige others, upon whom they bestowed gifts. Even the deliberate destruction of goods or gluttony was a strong signal of the social segregation of the elite. So it is not surprising that feeding the poor became a customary social act among the European elites of the Middle Ages.

### Charitable and Social Traditions

Byzantine emperors, for instance, invited the poor to their annual banquets on “vow day” (2 January). When an imperial prince was born, the event was celebrated by the distribution of *lochozema*, a “childbed soup,” in Constantinople’s main street. The ingredients, consisting of wheat flour, honey, butter, and sesame suggest the high prestige attached to this soup.

In many cultures, the birth of children or other rites of passage provide occasions for the public dispensation of food. Besides the wish to celebrate the happy event, elements of reciprocity also add to these customs. So, for instance, in eighteenth-century France it became customary for godfathers to throw “dragées” (sugar-coated sweetmeats), hazelnuts, almonds or aniseed among the children standing in front of the church. Yet these presents were eventually interpreted as the obligatory gift of the newcomer to those whose company they would share.

Some food festivals are of a religious nature. Every year the people of Morave, Slovenia, bring baskets of food into church to have them blessed for Easter. © CORBIS.

In the nineteenth century the custom was also integrated into wedding ceremonies. Another example of this reciprocal exchange is the *sikk pubn* feast (eating from the common pot) of the Cantonese ethnic groups in the rural suburbs of Hong Kong. For this feast, nine separately cooked ingredients, mostly luxury foods, are mixed in a big pot from which each guest, rich or poor, is invited to eat. Representatives of every single household and the village’s elders are invited to the feast. Hence, the hosts symbolically feed the entire community. *Sikk pubn* banquets are the only way to legitimize social transitions, since any marriage or birth that is not celebrated with a *sikk pubn* is not considered legitimate. The annual appointment of the village guardsmen also depends on the *sikk pubn*. If a significant number of lineage elders refuse the food, the selection procedures must be repeated.

Some existing festivals are rooted in the pious traditions of the medieval period, for instance, the feast of the Holy Spirit in the Portuguese-speaking world, especially in the Azores. There, the entire local community shares in an enormous banquet, which includes the distribution of food and money to the indigent. During the festivities a child is crowned as the “Emperor of the Holy Spirit.” The festival, now nearly extinct in Portugal, first appeared on the Azores during the fifteenth century. Its origins are closely connected to the ideas of the Calabrian monk Joachim of Flore (c. 1135–1202/5), who professed the arrival of the age of the Holy Spirit, an era of peace and prosperity.

### Cockaigne and Carnival

In addition to these social and charitable aspects, the themes of utopia and carnival became important elements of medieval and early modern festival culture. Of course, the idea of a utopian terrestrial paradise in which the lazy

The Guelaguetza festival is held annually in Oaxaca, Mexico. Shown here are young girls in native dress holding pineapples. © ROSE HARTMAN/CORBIS.

are rewarded and the diligent punished was already known to Greek and Roman authors like Lucian, Herodotus, and Strabo and was projected either onto foreign countries or the island of the blessed. But in the medieval and early modern period, the idea of a gastronomic utopia, the land of Cockaigne (*Cuccagna*, *Schlaraffenland*, *Lubberland*), developed in times of famine. This made an ideal theme for feasts of feeding. The “*Cuccagna Napoletana*” of the eighteenth century is a famous example. It was originally celebrated as the culmination of carnival in Naples with a procession of food carriages sponsored by the guilds of bakers and butchers. In 1746 the king ordered the food to be heaped up in front of the royal palace. For obvious reasons, the *cuccagna* had to be protected by guards until the king gave the sign from the balcony of his palace and the crowds were allowed to plunder the mountain of food. The *cuccagna* was conceived as a work of art, and all the victuals were displayed in the form of landscapes, gardens, or architectures. From 1759 a firm construction was used to drape the foodstuffs. The term *cuccagna* was also applied to more traditional forms of food distribution. So the disposal of food hanging from a wheel placed on the top of a post was called a *cuccagna* just as was the famous Carnival *degli gnocchi* of Verona. The latter is believed to date back to the year 1531, when the rich Veronese citizen Tommaso da Vico handed out flour, butter, and cheese to the starving masses of his hometown. Even though there is no documentary evidence for this festival prior to the eighteenth century, the event today is advertised as the “oldest carnival of Italy.” Once the “gnocchi” were cooked and dis-

tributed, the sponsors of the festival, pompously dressed, took part in the procession of the “macaroni.”

Numerous European festivals originate from charitable foundations or social obligations. An example of the latter is the Sindelfingen cake-ride in southern Germany, reflecting the millers’ duty to deliver cakes and bread to the local authorities as well as to the pupils of the town. First mentioned in 1535, the annual delivery developed into a traditional horse race, until in 1837 “enlightened” officials abolished this custom. Nevertheless, the millers were obliged to continue the payment of a fee to the graduating pupils up until 1961. Only five years afterward, the cake-ride was reactivated as a tourist attraction and has been celebrated ever since.

### Aspects of Economy and Amusement

Modern food festivals are generally characterized by the predominance of economic interests. There are few wine, beer, fruit, or vegetable festivals that originated prior to World War I. One of them is the Circleville Pumpkin Show (1903), in Circleville, Ohio. Despite its humble origins, this agricultural street fair soon developed into one of the largest festivals of the United States, attracting hundreds of thousands of visitors each year.

Countless agricultural festivals arose during the Depression of the 1930s. The intention was to promote consumption and to advertise products from certain areas. In the United States, such festivals were mainly founded by local voluntary associations like the Lion’s Clubs, whereas in Europe the government played a more decisive role in

their creation. For example, in 1930 the Italian ministry for agriculture ordered an annual countrywide celebration of a grape festival on 28 September. Nevertheless, the virtual mushrooming of food festivals is a recent phenomenon. The redefinition of ethnic and communal relations in a post-colonial and post-totalitarian world, as well as the revival of interest in regional foods since the 1970s, has contributed to this growth. Marketing also recognized the importance of festivals in providing firsthand experience with foods that would later be recognized by the potential consumer in the store. Yet, sheer human creativity still can lead to spontaneous festivities. The most spectacular food events of the present, the “tomatina” of Buñol, Spain, and the “battle of the oranges” at the carnival of Ivrea, Italy, are examples. Their key element is an orgiastic row, in which 55 tons of tomatoes and 350 tons of oranges are consumed, respectively, each year—and the numbers are rising. Food is used as a projectile and to soil others. The event of Buñol came into being in 1944/45, when a carnival parade got out of hand. In Ivrea the “battle of the oranges” dates back to around 1850 when upper-middle-class children practiced throwing oranges from the balconies of their houses. Today the contracting parties are organized in eight teams, each consisting of 100 to 300 members, who have to contribute to the festival’s costs. Their main targets are the people on the thirty-two horse-driven floats moving through the masses. Here adults turn into children for a few hours. Georges Bataille explains this behavior as the most archaic element in festival culture and world economy. Since enjoyment of waste engenders the will for surplus production, excess is the essence of a festival, as Sigmund Freud writes in his essay “Totem and Taboo.”

**FIBER, DIETARY.** In 1972 British physician Hugh Trowell defined dietary fiber as “that portion of the food which is derived from cellular walls of plants which is digested very poorly by human beings” (*Revue Européenne d'Etudes Cliniques et Biologiques*). Most of the current interest in dietary fiber stems from the efforts of Trowell and other researchers in the 1960s and 1970s to examine the differences in disease patterns between populations consuming diets high in refined foods (typical of developed countries) and populations consuming diets high in unrefined foods (typical of less developed or undeveloped countries). Populations with a higher intake of unrefined food, and thus a higher intake of dietary fiber, had lower risk of chronic diseases, such as heart disease, intestinal cancers, and gastrointestinal disorders, as compared to populations consuming highly refined, low-fiber diets. These observations stimulated a large number of research studies and, while the ability of fiber to prevent chronic disease is difficult to prove, the data gathered since the 1960s strongly supports the importance of dietary fiber for the health of the gastrointestinal tract and thus its importance in the general diet.

#### Definition of Dietary Fiber

In 2001 the U.S. National Academy of Sciences Institute of Medicine (IOM) recommended that “dietary fiber” be defined as the nondigestible carbohydrates and lignin that are intrinsic and intact in plants and that the term “added fiber” be used to characterize isolated, nondigestible carbohydrates that are added to foods or supplements. Defined as such, dietary fiber includes nonstarch

polysaccharides (NSP) and oligosaccharides that cannot be digested in the small intestine by alpha amylase or any of the sugar-hydrolyzing enzymes in the gut. The most commonly consumed NSPs include cellulose, pectins, glucans, hemicelluloses, and gums. Inulin, a nondigestible carbohydrate of lower molecular weight than NSP, also is included in this definition of dietary fiber. The only noncarbohydrate component of dietary fiber is lignin; however, this is probably a minor component of most edible portions of plant foods since it is associated with tough or woody tissues. An important distinction of the IOM definition is that dietary fiber is the term applied to plant foods in which the nondigestible carbohydrates remain intact and part of the structure of the plant cells. Because of inconsistencies in the precise definition of dietary fiber within the research community, the methods to analyze the fiber fraction of foods have been controversial. Earlier food composition tables provided crude-fiber values; however, this value does not include most of the dietary fiber in foods and should not be used to estimate fiber intake. Food tables that contain data using the enzymatic total dietary fiber (TDF) method or that include analysis of NSP provide more accurate estimates of fiber intake.

Dietary fiber is characterized as soluble or insoluble depending on its extraction by one of the steps in the TDF analytical method. Originally it was believed that this characterization might predict physiological effects of different fibers; however, this has not been the case, and more detailed descriptions of chemical-physical properties are needed to understand the metabolic response to diverse sources of fiber. Some fibers that are categorized as soluble fibers, such as hydrolyzed gums or oligosaccharides, are not very effective in lowering cholesterol. On the other hand, fibers vary in their physical properties, which appears to be important in understanding how fiber can affect metabolism. Certain polysaccharides can become viscous or thick when mixed with water. Viscosity is associated with slowing gastric emptying, lowering plasma cholesterol, and reducing the increase in blood glucose due to consumption of digestible carbohydrates. NSPs that can become viscous include glucans, pectins, and gums. Nondigestible carbohydrates can be fermented by the microflora in the large intestine, and these carbohydrates are the primary substrates for their growth and metabolism. To be fermented by microorganisms, polysaccharides must have water-holding capacity (WHC) so that microbes can penetrate the fiber matrix. Those polysaccharides with relatively high WHC are degraded to a larger extent than those with low WHC. In addition to viscosity, fermentability, and WHC, dietary fiber provides bulk in the intestines, and some fibers may bind bile acids and increase their excretion. Most foods contain a mixture of different types of polysaccharides; however, certain foods are good sources of particular types of fiber. For example, oats and barley contain mixed beta-glucans, fruits provide pectins, wheat

bran is high in cellulose and hemicelluloses, and dry beans are a source of viscous polysaccharides. Cellulose is the most abundant NSP in foods.

Fiber Content of Food

The table that follows provides values for some foods that are sources of fiber, including fruits, vegetables, cereals and grains, and dry beans and nuts. Based on the proposed definition from IOM, animal products contain no dietary fiber; it is derived only from plant foods. Some food products that are formulated with animal products could be a source of fiber if plant foods with dietary fiber or isolated polysaccharides are added in the preparation. The values in the table are reported as grams per 100 grams of edible portion so that it is easy to compare foods. Information is given in the conversion column so that the value can be converted to the foods as normally eaten. The table helps to illustrate how the handling and preparation of foods influence fiber content. As the data show,

TABLE 1

Fiber content of some foods			
Food description	Dietary fiber	Water	Conversion information
g/100 g of edible portion			
Fruits			
Bananas	2.4	74.3	1 medium = 118 g
Apples	2.7	83.9	1 medium = 138 g
Oranges	2.4	86.8	1 medium = 140 g
Orange juice	—	88.4	8 ounces = 248 g
Grapes	1.0	80.6	1 grape = 5 g
Plums, dried	7.1	32.4	1 dried plum = 8.4 g
Vegetables			
Tomatoes	1.1	93.8	1 medium = 123 g
Broccoli, cooked	2.9	90.7	1 spear = 37 g
Corn, cooked	2.4	76.7	½ cup = 82 g
Snap beans, cooked	2.8	89.9	1 cup = 124 g
Lettuce, romaine	1.7	94.9	½ cup = 28 g
Potatoes, baked without skin	1.5	75.4	½ cup = 61 g
Potatoes, French-fried, oven-baked	3.2	57.1	10 pieces = 50 g
Peas, cooked	5.5	77.9	1 cup = 160 g
Cereals and Grains			
Bread, whole wheat	4.3	37.1	1 slice = 25 g
Bread, white	2.3	36.7	1 slice = 25 g
Bread, rye	5.8	37.3	1 slice = 32 g
Rice, white, cooked	0.4	68.4	1 cup = 158 g
Rice, brown, cooked	1.8	73.1	1 cup = 195 g
Oatmeal, cooked	2.3	77.0	
Bran flakes	14.1	2.5	1 cup = 49 g
Corn flakes	2.8	3.2	1 cup = 28 g
Dry Beans and Nuts			
Kidney beans, canned	3.5	77.9	
Garbanzo beans, canned	4.4	69.7	1 cup = 240 g
Almonds, dry-roasted	11.8	2.6	1 cup = 138 g
Walnuts, English	6.7	4.1	1 cup chopped = 120 g
Peanuts, dry-roasted	8.0	1.5	1 cup = 146 g
SOURCE: Data obtained from the USDA Nutrient Database, release 13 at <a href="http://www.nal.usda.gov/fnic/foodcomp/">www.nal.usda.gov/fnic/foodcomp/</a>			

changing the water content of a food will change its fiber content. Dried plums have the highest fiber content for the fruits listed but also the lowest water content, due of course to the drying process. Likewise, the fiber content of potatoes is higher when the water content is lower. Cooking per se does not generally alter the fiber content of foods unless the water content is changed in the process. The cooking of vegetables will break down the cell wall structure and hence soften tissues; however, this does not remove the polysaccharides associated with the cell wall.

Food preparation methods that remove or separate parts of the food also can alter fiber content. Raw oranges and orange juice have similar water content, but no fiber is present in the juice because the process of squeezing the fruit extracts the watery fraction and leaves behind the fiber associated with the pulp. The milling of whole grains removes fiber, which is concentrated in the outer bran layers of the cereal grain. White rice has a lower fiber content than brown rice due to milling. Likewise, breads made with whole grains that have the bran layer intact will have higher fiber content than breads made with refined grains such as white wheat flour. In some starchy products the presence of resistant starch can contribute to the amount of fiber measured by the TDF method. Starch is digested normally by alpha-amylase in the intestine; however, some starch, because of retrogradation or the structure of the starch polymers, cannot be digested and passes into the large intestine as does NSP. Bran fractions are used in food product formulations to increase the fiber content of cereal products. A breakfast cereal made with wheat bran has a much higher fiber content than one made with a whole grain or a refined grain. Consumers can make quick assessments of such differences, as most food products are labeled with nutrition facts that give the per-serving fiber content.

### Fiber Intake and Health

Because fiber is nondigestible by enzymes in the mammalian small intestine, it mediates its effects on metabolism by its impact on the functioning of the gastrointestinal tract. Although fiber has not been considered a nutrient from a traditional perspective, it appears to be essential for the normal function of the small and large intestines. Fiber-containing foods take longer to masticate and involve more chewing than do highly refined foods. Because of the WHC of certain polysaccharides, their presence will increase the amount of water in, and therefore the volume of, the gut contents. The presence of viscous polysaccharides, as well as an increased volume of contents, will slow the rate of gastric emptying. The rate of gastric emptying determines the rate at which nutrients are exposed to the digestive enzymes and absorptive surface in the small intestine and hence the rate of nutrient absorption. Within the contents of the small intestine, the presence of nondigested carbohydrates will expand the bulk phase of the contents;

this type of dilution affects the mixing of gut contents and the process of digestion and absorption.

The net effect of these factors is that a diet high in fiber-rich foods is likely to slow the rate at which nutrients are digested and absorbed and cause digestion and absorption to occur along a greater length of the small intestine. Extending the period in which nutrients are available for absorption might result in a prolonged feeling of fullness and improve the satiety effects of meals. Because fiber is not digested in the small intestine, it passes into the large bowel, where it can remain undigested or serve as a substrate for the microflora that are normally present. Fiber is the only dietary component that increases stool weight. Its ability to improve laxation in this manner is either direct, by providing bulk as non-fermented carbohydrates, or indirect, by allowing growth of the microflora, which contribute to stool bulk. Scientific reviews have estimated that at least eighteen to twenty grams of NSP per 2,000 kilocalories should be consumed daily for adequate stool formation. Thus the properties of fiber result in a slower transit of food through the stomach and small intestine; however, transit through the large intestine may be shorter due to a high fiber intake. The net effect of fiber is to shorten total transit time through the gastrointestinal tract since residence time in the large bowel accounts for more than 90 percent of the total transit time.

Epidemiological or population-based studies have demonstrated that diets rich in plant foods are associated with a lower risk of chronic diseases such as cardiovascular disease, certain cancers, obesity, and Type 2 diabetes. The clinical and experimental studies to examine this relationship indicate that dietary fiber is one of the components of plant foods associated with reducing this risk. The ability of fiber to be protective relates to its functions within the gastrointestinal tract. Sources of viscous polysaccharides such as glucans, pectins, and gums reduce plasma cholesterol (and specifically LDL-cholesterol) levels by reducing absorption of cholesterol and bile acids, which are made from cholesterol. Viscosity helps to blunt the increase in blood glucose after a meal, which reduces the amount of insulin needed to clear glucose from the blood. Diets high in fiber-containing foods such as whole grains, fruits, vegetables, and dry beans tend to be lower in total fat and saturated fatty acids, which is a dietary pattern associated with a lower risk of cardiovascular disease and cancer. These foods also appear to be more filling and may help to regulate short-term appetite. Although fiber has not been proven to facilitate weight loss, its potential effects on appetite may help with weight maintenance. Because of fiber's importance to the microflora in the large bowel, there is considerable interest in its ability to protect against colon cancer. However, the primary evidence for this role of fiber is from epidemiology or experimental animal studies rather than from clinical studies. When microbes metabolize fiber, short chain fatty acids (SCFA) are

produced. These SCFA are used by cells in the colon and have been associated with maintaining a healthy mucosal layer in the gut. Advancing our understanding of the role that these compounds play in the health of the gut and in prevention of bowel diseases continues to be an active area of research.

In summary, dietary fiber has specific attributes that promote the normal functioning of the gastrointestinal tract. In addition, actions of fiber contribute to the ability of plant foods to lower the risk of chronic disease; however, it is difficult to isolate the effects of fiber from the overall response to a diet rich in plant foods, which provides many compounds that contribute to a lower risk of disease. As a consequence most recommendations of dietary fiber emphasize the importance of consuming foods high in fiber rather than relying on isolated fiber supplements.

## FISH.

*This entry includes three subentries:*

Overview  
Freshwater Fish  
Sea Fish

### OVERVIEW

When did human beings begin to eat fish? This question is an endless source of speculation. What can be said with confidence is that our very distant ancestors, if they lived near sea, lake, or river, would have picked up the idea quickly enough; watching the activity of diving birds, and finding fish trapped in rockpools or in naturally formed barriers in rivers, would have been sufficient prompts.

In prehistoric times, the availability of fish as food was distinctly limited. Of the marine species, only inshore ones ran any risk of being caught; deep-sea species, save for the occasional stranding on a beach, were not seen, much less caught and eaten. Even the most accessible of inshore species were relatively safe. So many fish, so few humans. And, to judge by archaeological evidence, humans found it easier to prize mollusks off rocks than to chase darting fish; witness the huge deposits of bivalve shells found in coastal Stone Age communities. Some of these deposits, for example those at Skara Brae in Shetland, are well known; but they are found in many parts of the world.

Freshwater fish enjoyed less immunity. Even before the arrival of nets and harpoons and fishing rods, they could be caught in fish traps made from simple, natural materials such as beavers used for making their dams.

Moving forward in time, it is clear that, at the dawn of recorded history, fishing and eating fish were well established practices. William Radcliffe's highly readable and wide-ranging *Fishing from the Earliest Times* (1926) shows that in most regions of the Old World—China, the civilizations of India and the Middle East, classical Greece and Rome—fish were a significant feature of the diet.

It is also abundantly clear that in early historic times the art of fishing and the scale of consumption developed rapidly. The works of early Chinese writers and of classical Greek authors, although some survive in mere fragments, exhibit a sophisticated range of specific fishing techniques and considerable discrimination among the species. Radcliffe observes that fishing techniques, at least for freshwater fish, have changed less over the centuries than corresponding techniques in, say, hunting (changed by the introduction of the gun); and that the spear, the line and hook, and the net remained preeminent fishing implements.

### Special Attributes of Fish as Food

Early humans may have known instinctively that fish constituted a beneficial food. There are many reasons for this. One reason, which no one would have been likely to articulate until recent times, is that fish need a less elaborate skeleton than land animals, since their weight is supported by the water in which they live, providing them more flesh in relation to body weight. They are therefore an excellent source of low-fat protein. (Incidentally, not all species of fish have true, bony skeletons. The category of certain important groups, notably sharks and rays, as "non-bony" indicate they have a skeleton of cartilaginous substance, not bone.)

There are other ways in which fish are unique among the categories of food. First, they constitute by far the largest resource of wild food in the world. Second, the huge number of species of edible fish distinguishes them from other foods. Not even the citizens of Norway or

Fisherman hanging fish to dry in the sun at Sunderbans, Bangladesh, 1996. © TIZIANA AND GIANNI BALDIZZONE/CORBIS.

Singapore (the top two countries worldwide in per-capita consumption) could hope to sample them all.

In addition, humanitarian considerations have been applied only rarely and selectively to fish and other marine or freshwater creatures, in contrast to the land animals (especially mammals) and birds. True, it has recently become unseemly for anyone except the Inuit (Eskimos) to eat marine mammals, and concern is sometimes shown over how to kill lobsters and crabs painlessly; but compassion rarely extends to fish. Nonetheless there may be a gradual change of attitude on this matter; indeed the first signs have already emerged of campaigns to include fish in “animal rights.”

This last point would fit in with the reverence that in many cultures has been accorded to fish, and with the symbolic importance they have enjoyed. It is common knowledge that a fish was the first symbol of Christianity, that several disciples of Jesus were fishermen, and that some of his best-known miracles involved fish as well as bread and wine.

In other religions and cultures too fish have had a special place. In ancient Egypt and elsewhere, fish were sacrificed for the gods. They could also take on the role of “scapegoats” or sin bearers. Thus in ancient Assyria people gathered on New Year’s Day by a lake or stream and, if they found numerous fish, took this as an omen for the expiation of human sins, and cast their clothes into the water for the fish to bear away, and their sins with them.

Fish could also be used, in Babylon and classical Rome, for auguries and oracular responses, based on a

study of their movements. However, it was in Christian cultures that the religious role of fish led to practical consequences. In medieval times the demand for fish, stimulated by the Christian Church’s insistence on meatless days, combined with realization that abundant stocks of fish such as cod existed in northerly waters, stimulated voyages of exploration and the development of techniques for fishing in distant waters.

So, at least in Europe, fishing and trade in fish took a new turn as the medieval period began. Northerly peoples such as the Scandinavians emerged from relative obscurity. The powerful Hanseatic League, centered on the Baltic Sea, was based to a considerable extent on its near monopoly of the trade in salted and dried fish; these fish came from the huge stocks of the North Atlantic. Indeed, the subsequent colonization of North America was certainly stimulated—some would say largely caused—by the search for ever more effective ways of exploiting these stocks and by the competition between the maritime powers for them.

The effects of all this activity are still with us. The salted and dried cod of medieval times survives today as an important article of commerce, under Scandinavian names such as *klippfisk*. In many parts of the world people who now have better means of preserving fish, notably freezing, continue to eat these products because they have acquired a taste for them. The same applies to the famous *lutefisk* which Swedes, for example, devotedly eat at Christmas despite all the bother involved in preparing it. Indeed it applies to many kinds of cured fish, including the hundred and one forms of cured herring such as kippers and bloaters, red herring and rollmops.

All this activity implies a recognition of fish as a valuable food resource. Indeed in the Orient, the Chinese have a consistent record, stretching back for more than four thousand years, of recognizing the nutritional (and often the medical) value of most seafoods, and of honoring fish. Bernard Read in his invaluable "Chinese Materia Medica" comments that:

Owing to its reproductive powers, in China the fish is a symbol of regeneration. As fish are reputed to swim in pairs, so a pair of fish is emblematic of conubial bliss. As in water fish move easily in any direction they signify freedom from all restraints, so in the Buddha-state the fully emancipated know no restraints or obstructions. Their scaly armour makes them a symbol of martial attributes, bringing strength and courage; and swimming against the current provides an emblem of perseverance. The fish is a symbol of abundance or wealth and prosperity, because they are so plentiful in the seas and rivers.

In the Western world, however, attitudes have been more ambivalent. Although the fish was a symbol of Christianity and prescribed as Lenten fare, opinions were divided on its merits, even on its suitability, as food. In Britain, for example, the evidence of eighteenth-century cookbooks indicates increased consumption of fresh fish from the sea, but the literature of dietetics shows a countervailing current among some medical authorities. As recently as 1835 the respected author of a manual on "modern domestic medicine" declared that fish "affords, upon the whole, but little nourishment, and is, for the most part, of difficult digestion, and this appears to be the general sentiment of intelligent medical men." One author even devoted a lengthy book to arguing that the fundamental cause of leprosy was "the eating of fish in a state of commencing decomposition." These examples remind us that it is only in the present century that seafood has been fully accepted in the West as an admirable source of nourishment. More specifically, it is only in recent decades that the importance of fish oils for health has been fully recognized. The recognition of fish as a valuable article in the diet has led to a flowering of books devoted to fish cookery. The prominence given by authors and by the media generally to fish as food, especially in the English-speaking world, is a new phenomenon which has its effect on demand.

The question arises: what are the future prospects for supplies of fish, and will they be adequate for the growing world population? There are many considerations involved here. Perhaps the most important is the development of aquaculture. Colin E. Nash has shown that there is a wealth of evidence from early sources in Egypt, China, and the Mediterranean region to show how the primitive origins of the industry led long ago to relatively sophisticated practices.

In classical Rome, for example, there were numerous *vivaria* (fish tanks), which served in part as status symbols for the wealthy but were essentially devoted to the

production of food. Later, from the early Middle Ages onwards, fishponds became almost ubiquitous in Europe, particularly in association with religious institutions such as monasteries. It does not need a genius to perceive the benefits, and it is not surprising that there is an ancient and strong tradition of constructing and stocking fishponds in Asia also. These, of course, are for freshwater fish, especially carp and (more recently) tilapia. However, even in classical Rome there were *vivaria* for marine species and progress was already being made in taking advantage of saltwater lagoons and suitable parts of estuaries to create enclosures in which seafish could be raised to maturity. Carol Déry has demonstrated that the Romans had progressed amazingly far in this sort of activity, perhaps further than modern people until the last quarter of the twentieth century. Now, however, the pace is quickening. Techniques for raising salmon in sea lochs or similar environments and for dealing with the attendant risks (pollution, infections, etc) are constantly improved. The number of species involved is growing as trials show that more and more can be successfully brought to marketable size in protected surroundings. Atlantic cod are being raised in Norwegian fjords, catfish are brought up in "farms" in the southern states of the United States, and so on. The future looks promising.

As for the sea fisheries, it is difficult to be equally optimistic, since so many fishing grounds are now being exploited up to and beyond the sustainable limits, and some stocks, for example cod in the northwest Atlantic, have already been overfished to the point of extinction. Politics enter into the matter in a big way. To put it very mildly, not everyone in the fishing industry is willing to sacrifice short-term gains for long-term benefits. The same applies to consumers, and it is significant that at the beginning of the present century a new international organization, the Marine Stewardship Council, set about establishing a broad set of Principles and Criteria for Sustainable Fisheries. A system of "eco-labeling" is advocated, whereby special labels will indicate to people buying fish whether these are from an endangered source or not.

Progress may be slow but it is being made, and there is one comforting thought. Humans are now better equipped than ever before to harvest the waters, and also better informed about the ways in which harvests can safely be maximized.

## FRESHWATER FISH

Fish have been a major source of human food and of oil, fertilizer, and feed for domestic animals since the dawn of history. Efforts to propagate fish as a source of high-grade protein for human consumption have been more recent but still date to ancient China and the Roman Empire. In the twenty-first century, fish provide about 25 percent of the animal protein consumed by people in developing countries and as much as 75 percent in countries such as Bangladesh and the Philippines.

One reason for the long-standing popularity of fish as food is sheer numbers. More than 70 percent of the Earth's surface is covered with water, and well over twenty thousand different species of fish live in marine, fresh, and brackish waters, making them the most diverse of all the animals. Fish can live at temperatures ranging from below freezing in Antarctic waters to over 100°F (40°C) in hot springs. They range in size from the .5-inch (1.3-centimeter) dwarf goby of the Philippine Islands to the 45-foot (14-meter), 25-ton whale shark of the tropical oceans. The nutritional profile of fish is also outstanding. Rich in the essential omega-3 unsaturated fatty acids so lacking in other foods, fish are also high in protein yet low in calories, sodium, sugars, saturated fats, and cholesterol.

### Biology

Scientifically speaking, fish are aquatic vertebrates with gills instead of lungs and fins instead of external limbs. In contrast to the higher animals, fish are also cold-blooded, that is, their body temperatures remain the same as that of the water. A few species, such as tuna, are able to maintain their body temperatures a degree or two higher than the water.

The chain of life leading to fish production begins with the microscopic diatoms and algae in lakes, rivers, and the ocean. These aquatic plants, collectively termed phytoplankton, use the energy in sunlight to convert carbon dioxide dissolved in the water into the organic matter that eventually becomes food for fish. Fish were the earliest animals with backbones to appear in the fossil record, evolving from more primitive forms over 500 mil-

lion years ago. In turn, the terrestrial animals evolved from the fishes.

Biologists class the more than twenty thousand known species of fish into three main groups, the Agnatha (primitive jawless fishes, such as the blood-sucking lamprey), the Chondrichthyes (sharks, skates, and rays that have skeletons of cartilage instead of bone), and the Osteichthyes (fishes with a bony skeleton, such as salmon and trout). All of the fish important as food are members of this latter group.

A typical bony fish is torpedo-shaped with a head containing a brain and eyes, a trunk with a muscular wall, and a postanal tail. Fish generally propel themselves through the water by undulating movements of the muscular trunk, using their fins to control direction. All have skins covered with a layer of mucus that decreases friction with the water, and nearly all are covered with an external layer of scales (catfish are one exception). Fishes also have a system of sensory organs along their sides, called the lateral line, that can detect pressure changes in the water caused by sounds. Fish obtain oxygen and eliminate carbon dioxide (breathe) by sucking water into the mouth and pumping it out over the gills. Oxygen dissolved in the water thus diffuses into the bloodstream, and carbon dioxide diffuses out. A few species (such as the African lungfish) also have air-breathing lungs as an additional means of respiration.

Most fish live in either saltwater or freshwater, but some important food fish are physiologically capable of migrating from one to the other. For example, Pacific and Atlantic salmon are hatched and reared in freshwater but then migrate to the ocean to grow and mature, returning to their natal streams and lakes to spawn. The eel has the opposite life history pattern. Thus eel and salmon may be thought of as either freshwater or saltwater fishes depending on age and season.

Over the years, a number of other aquatic animals have been given common names that include the term "fish," such as shellfish, but these do not resemble and are not related to true fish. Furthermore, some animals that have adopted an aquatic way of life, such as whales, seals, and sea snakes, superficially resemble fish and may even be called fish. But they are air breathers, and their anatomical structure is that of land animals.

### Preparation and Food Safety

Fish are a highly perishable food product, and historically they had to be marketed live or preserved (cured) by smoking, salting, pickling, or a combination of these methods. Fish to be cured by any method are first cleaned, scaled, and eviscerated. They are salted by packing them between layers of salt or by immersion in brine. Smoking preserves fish both by permeation of smoke ingredients and by partial drying due to heat penetration. Fish can also be dried per se by carefully controlling temperature, humidity, and air velocity.

Freshwater fishing is idealized in this nineteenth-century engraving of a brook trout fisherman by James Merritt Ives. © FRANCIS G. MAYER/CORBIS.

However, dried fish are relatively unappetizing, and rehydration is slow. With the exception of smoked fish, the ready availability of ice and modern freezing and canning facilities has largely supplanted curing as a method of fish preservation. Fish are routinely shipped around the world either fresh or frozen. Fresh fish are shipped on ice and have an acceptable shelf life of about ten days. Frozen fish packaged in oxygen-impermeable plastic wrap, such as Saran, may be stored frozen at  $-20^{\circ}\text{F}$  ( $-29^{\circ}\text{C}$ ) for up to six months with no appreciable loss in quality.

Fresh fish are almost always marketed as either whole fish on ice (viscera removed), dressed fish (head, fins, and viscera removed), fillets (sides cut lengthwise away from the backbone), or steaks (cut longitudinally into sections). Due to consumer demand, boneless cuts are increasingly available in the United States and Europe.

Fish is a naturally tender protein food, free of tough fibers that need to be softened by prolonged cooking. Thus fish products are best cooked using high-temperature, short-time methods. They may be deep-fat fried ( $325\text{--}350^{\circ}\text{F}$ ;  $163\text{--}177^{\circ}\text{C}$ ), pan fried (*sautéed*) in a small amount of butter, broiled, poached (simmered, never boiled), or baked ( $400\text{--}450^{\circ}\text{F}$ ;  $204\text{--}232^{\circ}\text{C}$ ). Pan frying or *sautéing* is one of the most widely used methods of cooking thin fillets in general. Microwaving is especially well suited to the high-temperature, short-time method of cooking fish. The advent of individually quick-frozen fish fillets has enabled timesaving cooking techniques, such as brushing marinades directly on the frozen

product and grilling or oven roasting without the necessity of defrosting. Fish is generally ready to eat when cooked to a temperature of  $140^{\circ}\text{F}$  ( $60^{\circ}\text{C}$ ) and the flesh has turned opaque and flakes easily. Fish is eaten raw by some ethnic groups (such as Asians). Other ethnic specialty preparations, such as blackened fish (Cajun) or gefilte fish (Yiddish), are also popular.

To ensure food safety, fresh fish should be clean smelling, and the flesh should be firm and resilient when pressed. Fish should be kept wrapped and refrigerated at  $40^{\circ}\text{F}$  ( $4^{\circ}\text{C}$ ) or less and eaten within two days. Frozen fish should be rock hard, free of ice crystals, and have no white spots, visible drying, or browning around the edges. In the home, fish should be stored frozen at  $0^{\circ}\text{F}$  ( $-18^{\circ}\text{C}$ ) or below and for no more than three months. It should be thawed in a refrigerator, never at room temperature.

### Freshwater Fish Commonly Used as Food

Historically, the human race has used literally thousands of different species of fish in its continuing search for sustainable sources of food. In the twenty-first century, the most popular in North America and Europe include carp, catfish, crappie, eel, lake herring, mullet, muskellunge, yellow perch, yellow pike, pickerel, salmon, suckers, sunfish, tilapia, trout, lake trout, and whitefish. In Indonesia, the Philippines, and Taiwan, milkfish have been used for food for centuries. In Asia, carp, ayu, and eel are important freshwater food fish. Some of the most interesting of these freshwater fish are discussed in more detail below.

**Ayu.** The ayu (*Plecoglossus altivelis*), also known as sweet fish in Japan and aroma fish in China, is an extremely popular and economically important freshwater food fish in many Asian countries. Historically, it was caught by Japanese fishermen using trained cormorants with rings around their necks to prevent them from swallowing. In the twenty-first century, it is wild-caught in rivers by sport and commercial fishermen or raised commercially for both restaurant consumption and home use. Ayu are usually sold live, on ice in the round, or frozen. The food quality of wild-caught ayu is especially desirable, characterized by a sweet, delicate taste and an odor reminiscent of cucumber or watermelon.

**Carp.** Carp (*Cyprinus carpio*) are the largest members of the minnow family and can easily reach a weight of ten kilograms or more. Although greatly underutilized in North America, the common carp has always been a widely popular freshwater food fish in the rest of the world. History records that carp were grown in ponds for food in ancient China in the fifth century B.C.E. In Europe, carp were grown in monastery ponds as early as the sixth century C.E. so the monks would have something to eat during the many meatless fasting days prescribed by the church. By the late Middle Ages, carp had become a well-established food item for the general populace. In the twenty-first century, carp are wild-caught or grown for food in Russia, Ukraine, Hungary, Poland, India, China, Japan, Latin America, Egypt, Iran, Indonesia, and Israel, to name only the major consumer nations. The world's leading producer is China, where carp are often grown in rice paddies in rotation or even simultaneously.

The most common market forms of carp are fresh whole fish, dressed fish, or fillets. Gefilte fish, fish balls blended with egg and matzo meal and simmered in a vegetable broth, is an ethnic specialty item (Yiddish) traditionally made from carp.

**Catfish.** The channel catfish (*Ictalurus punctatus*), native to warm water lakes and rivers in North America, is a traditional food fish in the southern United States. Consumer demand has moved from regional to national and even international. In the United States, the per capita consumption of catfish is exceeded only by that of tuna, shrimp, pollack, and salmon. To satisfy American consumer demand, several hundred thousand metric tons of channel catfish are produced by aquaculture each year in the southern United States.

Imported catfish from Vietnam has been marketed aggressively to restaurant chains and food service companies with considerable success. Advertised as delta-raised catfish, it is actually a catfish relative raised in the delta of the Mekong River. Another catfish species, the walking catfish, is a popular food fish in tropical regions and even in some European countries, especially the Netherlands.

Catfish is firm textured and has a mild, slightly nutty taste that complements a variety of flavors. It is a lean

fish, and modern processing methods have eliminated bones. That, together with its lack of a fishy odor, gives it wide consumer appeal. Catfish were traditionally wild-caught and marketed as iced whole dressed fish. Modern farm-raised catfish are processed within minutes and shipped either on ice or as individually quick-frozen fillets, making it one of the freshest fish available. In addition to fresh or frozen fillets, steaks and nuggets (pieces) breaded or marinated with flavors and spices, such as Cajun spices or mesquite, are also common in seafood markets and restaurants and have even been introduced into school lunch programs. As Mark Twain once said, "The Catfish is a plenty good enough fish for anybody."

**Eel.** Although appreciated before the Civil War in North America, freshwater eels (primarily *Anguilla anguilla* and *A. japonica*) are a widely popular food item in Asian countries, particularly Japan, Korea, China, and Taiwan. Eels are also an important delicacy in Europe, particularly Italy, where they must be produced commercially by aquaculture to satisfy consumer demand. Overall, however, China produces more than 70 percent of the eels sold in the world, and many rice paddies have been converted to eel production. Japan is the world's largest eel consumer, where *kabayaki*, eel fillets grilled with a sweet basting sauce, is practically a national dish.

As mentioned, eel consumption in North America is minor. However, freshwater eel *unagi* is common in Japanese restaurants in the United States, where it may be served grilled with teriyaki sauce or used in sushi or *unadon* (eel over rice). In addition, each year many tons of market-sized eels are wild-caught by U.S. fishermen and exported to Europe, where it is eaten roasted or even jellied and baked into pies.

Eels have an interesting life history in that they live in freshwater rivers and lakes, where they grow to adult size, then they migrate into the ocean, where they swim long distances to the Sargasso Sea to spawn and die. The newly hatched young eels may then ride the ocean currents for several years until they reach coastal waters and swim back to freshwater rivers. There they grow to adult size and can be harvested for food.

Eels under a kilogram in size are the most tender. The rich, sweet, firm flesh of eel must be refrigerated and eaten immediately, so the best restaurants keep live eels in aquarium tanks. The skin and outer layer of fat are removed by the chef, and the fillets are either grilled or roasted. Eel is also available frozen, smoked, or jellied in cans.

Asian folklore holds that eel consumption confers strength and vitality, particularly in hot summer weather. Eels are amazingly rich in vitamin E and in the omega-3 fatty acids (DHA) that are essential to brain functions involving mood.

**Milkfish.** Milkfish (*Chanos chanos*) have been an important food fish for people in Southeast Asia for many

Traditional fish cage made of split bamboo and reeds (China, twentieth century). Fish were placed inside the cage, which was then submerged in water to keep them alive for market. ROUGHWOOD COLLECTION. PHOTO CHEW & COMPANY.

centuries. Although they are an oceanic fish, milkfish spawn in shallow coastal areas, where fry and fingerlings are collected in nets and carried to freshwater or brackish water ponds for rearing to market size. Milkfish have been raised in this fashion for at least seven hundred years in the Philippines and Indonesia. Taiwan is also a major producer. Milkfish (*bangus*) is sold in Asian markets and restaurants either fresh, smoked, marinated, as fish balls, as fish sausages, or as fish nuggets. It is also exported frozen to North America, where *sinigang na bangus* (milkfish in sour broth) is a popular dish among ethnic Indonesians and Filipinos.

**Tilapia.** Although relatively new to North American fish markets, tilapia are actually a group of fish (cichlid) that traces its origins to North Africa and the Middle East. These mild, white, sweetly flavored fish have been wild-caught or pond-raised around the world for centuries. Called St. Peter's fish in many parts of the world, legend has it that the fish Jesus multiplied to feed the multitudes in the story of the seven loaves and fishes was tilapia (Matt. 17:24–27).

Because of their versatility, tilapia have been nicknamed "the aquatic chicken" and can be baked, broiled, fried, blackened, grilled, poached, or sautéed. Sautéing is

one of the most popular methods of preparing thin fillets in general, and in most recipes tilapia can easily substitute for catfish or even sole and flounder.

Tilapia are grown in floating cages, ponds, or rice fields in temperate and tropical regions around the world. Only Chinese carp and salmon or trout exceed tilapia in total worldwide fish production. Although they are less popular in the United States, tilapia consumption has grown to rival trout among the commercially raised fish species. Since relatively modest numbers of tilapia are produced by U.S. aquaculture, large quantities of frozen fillets are imported from Indonesia, Taiwan, and Mexico to satisfy consumer demand. Many large U.S. cities report a significant demand for live tilapia delivered to ethnic Asian markets.

**Trout.** Many trout species have historically been used for food, but rainbow trout (*Oncorhynchus mykiss*) have been by far the most popular. Originally native to cold water environments in the north temperate zone, this prized food fish has been transplanted around the world and is well established in North and South America, Japan, China, Europe, Australia, New Zealand, and parts of Africa. Top trout-producing countries include Chile, Denmark, France, Italy, and the United States.

Most rainbow trout is marketed as head-on dressed fish, as fresh or frozen boneless fillets, or as smoked fish. Farmed trout are typically rich in the omega-3 fatty acids so essential to normal brain and eye function, while they are less expensive than most other fish products.

**Walleye pike.** Walleye (*Stizostedion vitreum*), a member of the perch family with an excellent reputation for its food quality, is a widely sought cool-water fish mostly caught by anglers for home use but also available in fish markets and restaurants in much of the northern United States and Canada. In the United States, a limited commercial harvest comes from the Great Lakes. However, most of the commercial harvest is from Canadian fishing on Lake Erie and the inland waters of Ontario and Saskatchewan. The walleye is Canada's most economically valuable freshwater fish. Only a few commercial growers produce food-size walleye, but because of its reputation for excellent food quality (aroma, flavor, and texture), its name recognition, and its high retail price, walleye has considerable aquaculture potential. Traditionally, walleye are sold as scaled, skin-on fillets. A two-pound fish yields about two eight-ounce dinner-size fillets.

**Whitefish.** Lake whitefish (*Coregonus clupeaformis*) native to the deep cold lakes of North America are popular food fish in the United States and Canada. They are widely sold in restaurants, and some believe their flaky, non-oily white meat is the best tasting of all the freshwater fish. Early settlers claimed they could eat nothing but whitefish for days at a time and never tire of it. A large commercial fishery for whitefish exists in Lake

Superior and the other Great Lakes of the midwestern United States. In Canada, close to 600,000 kilograms of whitefish a year is caught and sold by tribal fishermen of the Great Slave Lake alone. Most whitefish is marketed frozen and sold in restaurants or supermarkets, but limited amounts are also available smoked or fresh. Whitefish eggs, termed freshwater or golden caviar, are sometimes sold as a less-expensive substitute for sturgeon caviar.

#### SEA FISH

In all the oceans of the world, fish have abounded for countless millennia, most of them doomed to spend their whole lives swimming until they are eaten by bigger fish. Shakespeare put it well when he had the Third Fisherman in *Pericles* ask how the fishes live in the sea, to which the First Fisherman replies: “Why, as men do on land; the great ones eat up the little ones.” Only a tiny minority of fish are sufficiently large or well protected to escape predators. Even they may fall prey to the latest predators to arrive on the scene—to wit, ourselves.

Until human populations began to increase at an exponential rate, and until methods of preserving and transporting foods approached their present level of sophistication, mankind’s need for food had little impact on the vast resources of the oceans and seas.

Radical change in this situation began in medieval times, when European fishing boats reached the rich cod-fishing grounds in the northwest Atlantic. Salting techniques, as well as wind-drying, meant that huge quantities of fish could be processed in, for example, Newfoundland and then brought back on the long voyage to Europe. Meanwhile the ascendancy of the Roman Catholic church, with its numerous fast days, in an increasingly populous Europe caused a sharp increase in demand. Salt cod became, and remains to this day, a staple food in the Iberian Peninsula, the south of France, and Italy.

In more recent times fishery techniques evolved swiftly, culminating in the modern fishing industry. This has such deadly accuracy in finding shoals of fish and in catching them, and such advanced means of freezing, that overfishing occurs wherever effective controls have not been instituted. These controls are hard to establish and maintain. The initial impact on fishermen is adverse. Boats have to be laid up; an appreciable number of fishermen lose their livelihood; fishing ports where many people earned a living by servicing the fleets risk falling into a slump. However, if supplies are to be maintained, fish stocks must be allowed to survive in viable number and every ancillary means, notably more and better fish “farming,” must be developed.

Considering the merits of fish as a food, nutritionists give it high marks. Sea fish, like freshwater fish, are an excellent source of protein, but have additional health benefits to offer, for example in the form of vitamins, iodine, and phosphorus. Joyce Nettleton (1987) gives a comprehensive survey of the vitamins in which seafoods are rich, including pyridoxine, niacin, and vitamin B<sub>12</sub>.

So far as fat and oils are concerned, there is a major distinction between what are sometimes called “white fish” (for example, the cod family and flatfish) and what the Spaniards refer to as *pescado azul*, meaning blue fish. The latter category includes the powerful surface swimmers such as tuna and mackerel, which roam at speed over deep waters and whose coloration is usually dark blue with a pale underside, to make them inconspicuous to predators from above or below. Their lifestyle calls for very strong muscles, creating a need for more oil in their bodies. As a group they may be categorized, less romantically than in Spain, as “oily” fish.

There is, as one would expect, no sharp dividing line between oily and nonoily, but a spectrum with “white fish” clustering at one end and “blue fish” at the other. The oil content may be as high as 15 percent (sardines at certain times of year) or as low as 1 percent or even less (flatfish); in general, a content of over 5 percent would be enough to rate a fish as oily. The oily fish contribute more fat to the diet, which makes dieters wary of them, but the fish oils are in fact highly beneficial from several points of view, so much so that people who do not include oily fish in their diet may be advised to take fish oil supplements. Joyce Nettleton provides a clear and

full exposition of the merits of the omega-3 fatty acids (present in seafood because it is made in the first place by the phytoplankton in the oceans) and their special virtues.

Summarizing the health benefits of eating sea fish, Nettleton points out that they are low in calories, that most of them are very low in fat, while all are low in saturated fat. The long-chain omega-3 oils have been shown to protect against heart disease and some other afflictions, and are definitely low in cholesterol and in sodium. She refers also to the vitamins and minerals mentioned above, explaining that dark-fleshed fish have especially abundant amounts of iron, and that seafood is the best source of many trace minerals such as zinc, selenium, fluoride, and copper.

Sea fish in general, and “white fish” in particular, are usually easy to digest, partly because they have very little connective tissue. Indeed certain white fish with delicate flesh (for example, whiting) are traditionally recommended as invalid food. Moreover, they can be eaten cold as well as hot.

Fish bought from a fishmonger or in a supermarket are usually from a limited number of familiar species, and bear labels saying what they are. But for some people, for example, travelers and expatriates, choosing and identifying fish can be a problem; and of course a sure means of identification is a necessity for all who are involved in the international fish trade. In these other situations there is potential for confusion, arising mainly from the sheer multiplicity of edible species. There are not many sorts of meat in common consumption, and the number of species of bird which are widely eaten is limited. But the number of edible fish is very large, and even in one market there may be scores available.

The number of species is quite enough by itself to cause perplexity, but there are aggravating circumstances of two kinds, which compound confusion. One source of confusion may be regarded as natural and viewed with tolerance. This is the confusion caused by the fact that even within one language, indeed sometimes within one dialect, the same fish will have a range of different names. These reflect local practice in small coastal communities, which were often isolated from each other in the past by poor overland communications. In Italy, for example, the common grey mullet, *Mugil cephalus*, has more than forty different names.

The other sort of confusion applies to European languages, especially English, and is a by-product of colonization. Its effect is quite the contrary—to make it seem that there are fewer families or species of fish in the world than there really are. What happened was that early English colonists, to take the main culprits as an example, applied familiar but inappropriate names to the species that they encountered in the New World, Australasia, and elsewhere. Understandably, they called the fish they found overseas by names they already knew, on the ba-

sis of a real or fancied resemblance. This could sometimes work satisfactorily. English settlers in North America, familiar with salmon at home, found salmon there too, not always of the same species, but at least of the same family (Salmonidae). But sometimes the results were less happy. The fish that settlers in Australia called salmon are not akin to the salmon of the Northern Hemisphere, while the so-called “Murray cod” of Australia is not a cod and is not even a sea fish.

In a situation affected by so many causes of confusion, it is only the scientific names of the species that can provide certainty. Fortunately, international and national authorities have been working for some time to rationalize commercial names for the species, and more and more authors are adopting the practice of identifying the species they mean, if there is any room for doubt, by its scientific name as well as by popular ones. The work of the Fisheries Division of the Food and Agriculture Organization (FAO) of the United Nations has made, since the 1950s, an outstanding contribution to clarification and precision.

In any case, and in practical terms for consumers, the sort of confusion described above is not the norm; nor does it necessarily cause bad results. A number of species occur around the world, for example, *Xiphias gladius*, the swordfish, and *Mugil cephalus*, one of the grey mullets. Nearly all the families of fish have representatives in both the great ocean areas, and these representatives differ little from the cook's point of view (although the scientists properly distinguish between them by counting their fin-rays or examining their air-bladders). Thus the famous red mullet of the Mediterranean have close relations in the Indo-Pacific; but the latter are known as goatfish, and treated by Asian cooks in a different way, and for this reason people often fail to see the connection.

There are certainly wide variations in the manner of fish consumption. In many European countries it would be normal to serve a small fish whole and a larger fish in full portions (say, 5 oz [150 g]) either separately (to be followed by a vegetable, as often in France) or with vegetables. In Britain, for example, the tradition is that fish is either what you have with chips or something to be served, like meat, with “two veg.” But these traditions, although spread around the world to some extent by the influence of France and of the British Empire, are not widely shared. In most parts of the world, especially Asia and Africa, fish is more likely to be one constituent of a combination of different foods, or an element in a one-pot dish, or something that accompanies pasta, or rice, or goes into fish balls, fish puddings, or pies, or is part of a soup-plus-fish-stew dish. Many such modes of presentation produce delicious results, and make a relatively small quantity of fish “go further.”

This last point has an even wider application. In most countries of Southeast Asia a product known as fish sauce

Herring barrels stacked along the docks of Aberdeen, Scotland, circa 1900. The barrels await shipment to Europe and North America. ROUGHWOOD COLLECTION.

(*nuoc mam* in Vietnam) plays an important part in the diet as a source of protein. These sauces are prepared by fermenting large quantities of small fish, usually such as would serve no other purpose, and straining the liquor which this process generates. This liquid resembles soy sauce, both in appearance and in its composition. Added to rice or other savory dishes, it enhances both flavor and nutritional qualities.

The preparation of fish sauce is one example of how fresh fish can be turned into a product that will keep for a long time. The various sorts of fish paste are others. The fish used for these purposes lose their identity, whereas those that are dried or salted or smoked (or undergo all three processes) can still usually be seen for what they are. They may also become better to eat, or anyway come to be preferred, as in the case of the kipper (salted, dried, and smoked herring) or the salt cod mentioned above, which has for centuries been a staple food in the Mediterranean region, or the smoked salmon that is now an almost inevitable feature of restaurant menus. That freshwater fish are less often subject to preservation

processes may simply reflect their greater availability—trout can be found in the river (or, nowadays, fish farm) at any time and marketed on the same day, whereas many marine fish can only be harvested by distant fishing boats.

Some species of fish are purely freshwater, others are entirely marine. But the division is not clean-cut, for there are species, and important ones, of sea fish that can, and in some instances must, move from one environment to another. In many instances species that live most of their lives in the sea have to go up rivers to spawn. They are called anadromous. Some famous examples are salmon, shad, and eel. However, the eel differs from the other two in that its stay in freshwater covers the greater part of its life. It is a marine fish only in Act One of its life, when it drifts in larval form across the Atlantic from the Sargasso Sea to the river mouths of Europe, and in Act Five, when it goes back into the sea years later and sets off on its arduous journey back to the Sargasso Sea, there to spawn and die. Indeed, although the sea thus provides both its birthplace and its grave, the eel counts for many purposes as a freshwater species.

If only because of this sort of anomaly, there is little point in asking which are better, freshwater or marine species. It is true, however, that there is some division of opinion, misguided or not, about their respective merits. In inland countries and regions the former may be preferred because they have been accessible for much longer and are established as traditional dishes. Where sea fisheries are established, the reverse is usually the case. However, there are exceptions. To take two examples, people in Bangladesh and Burma prefer freshwater fish and use spices, notably ginger, to mask the marine flavor of sea fish, the very flavor that people in many other countries prize.

Even within the category of sea fish it is interesting to note that some people believe that fish from cold waters are better, the idea being that they lead a particularly active and healthy existence, whereas fish from semitropical or tropical waters laze about and have a less firm consistency. If this belief were to be investigated, it would probably turn out to have little or no foundation.

There is one respect, however, in which sea fish from colder and warmer waters do differ significantly. In cold waters it is usual to find a relatively small number of species, normally existing in huge populations. In tropical or near-tropical waters, on the other hand, there is a very great diversity of species, but few of them are anything like as numerous as those of cold waters.

However, as usual when trying to make generalizations about sea fish, one finds that this contrast is not entirely valid. Some species of tuna are among those which pass, apparently without any problem, from cold to warmer zones and back again. The whole great family of tuna is extraordinary in other ways too. One is the degree of ceremony, drama, and cultural significance with which the fishery for them in the Mediterranean is invested. The tuna traps, of which about a hundred were still operating in the 1960s, were certainly in use in classical times, and some authorities believe that they date even further back. Essentially the trap consists of a long net stretching out to sea, across the expected path of the migrating bluefin tuna. This net diverts the fish into a series of pounds, each of which leads into the next, and finally into the death chamber. There, a net stretched across the bottom can be hoisted up periodically, when there are enough tuna present, bringing them up to a position where they can be taken with gaffs. The fishermen jump in to deliver the death blows. The scene is bloody and to spectators horrifying. The Greek tragedian Aeschylus likened it to the slaughter of the Persians at the battle of Salamis. In Sicily, where the event is called the *mattanza*, and in other places around the Mediterranean the capture and slaughter of the tuna is an event that has more significance than a mere fishery episode; it has served to reaffirm, annually, the cultural identity of the whole community.

In contrast, in most communities in the Western world, the catching and killing of sea fish take place com-

pletely offstage; indeed, many of them finish up as neatly trimmed fillets whose identity would be a mystery unless revealed by the label. This distancing of the scene in a dining room from that on the deck of a trawler has left people without the feeling for fish so eloquently expressed by classical writers. This was still evident in nineteenth-century writings such as the Reverend Badham's *Prose Halieutica: Ancient and Modern Fish Tattle*. However, the Greek word in the title is a direct echo of the Greek poet Oppian's *Halieutica*; Badham wishes his readers to know that his own picture of the fishy world, in which the personalities and habits of so many of the fish are described, stems from classical times. If modern writers allude at all to these aspects of the fish, it is only in terms of the struggle fishermen are perceived as waging against the fish, so that the attributes of the fish are generally restricted to terms such as "wily," "valiant," "predatory," etc.

It was in classical Greece that the earliest known guide to finding good food was composed. The author was Archestratus. Enough of the work survives (and has recently been published in translation) to demonstrate the point that is relevant here: that more attention was paid to good sources for fish of the highest quality than to any other category of food. The recommendations were not just of the "Syracuse is the best place to buy fish" variety, but were completely specific. Thus connoisseurs were directed to the straits of Rhegium for sea-caught eels and to Ephesus for a fat gilthead bream. This argues a greater public awareness of quality in fish, and of the various species, than is common nowadays. It is of course relatively easy to have this commendable awareness in a small city-state with an economy based on slave labor and ready access to freshly caught fish. In the modern world, with much of the population inhabiting huge conurbations, far from the fishing ports, and relying in the main on what supermarkets find it economic to provide (there are far fewer fishmongers nowadays), it would be fruitless to expect to find many connoisseurs of fish. Nevertheless, there is one favorable trend, noticeable in the last decades of the twentieth century and the first of the twenty-first. This is the gradual recognition of fish that qualify for an "organic" label as desirable, leading to greater appreciation of quality in fish. This is accompanied by a growing proliferation of cookery books whose recipes frequently call for a particular species of sea fish, and not necessarily one which is in common supply. To take one example, what has happened to the anglerfish (often called monkfish and, in America, goosefish) is instructive. It used to be spurned on both sides of the North Atlantic and was appreciated only in the Mediterranean. Now it has become a valuable and relatively expensive kind of fish, and recipes for it abound. The ability to make greater use of species that had been underexploited in the past is one necessary element in maximizing the harvest of the seas, to the benefit of all.

Alan Davidson

**FISH, SALTED.** Sodium chloride (NaCl), also called salt, common salt, and table salt, is generally recognized as a safe (a status sometimes abbreviated by the acronym GRAS) antimicrobial and incidental food additive (Klaassen). Salt has been used for centuries as a seasoning and flavor enhancer as well as a preservative or curing agent. Salt has played a major role in many aspects of human life: nutritional, economic, political, and military. Egyptians preserved food by salting or sun-drying; Roman soldiers were paid in salt; Napoleon's campaign in Russia suffered a setback because of lack of salt; and salt was used in trade and exchanged for slaves in ancient Greece (Pszczola; Salt Institute). The Greeks also salted fish and used them as a part of their diet. Later, they passed this practice on to the Romans (Jay).

### Fish Preservation

Fish are highly perishable, and they will spoil rapidly if improperly handled. Fresh iced fish generally are spoiled by bacteria, but dried fish are usually spoiled by fungi (Jay). Salting as a method of preserving fish has been used for centuries and in many places around the world such as Asia, Europe, and Latin America. The simplicity of the salting process, the low cost of production and the ease with which it combines with other preservation methods, such as drying or smoking, has led to its popularity and extensive use (Berhimpon et al.).

In the usual process of dry-salting, whole fish are eviscerated, cleaned, washed, dry-salted, stacked in containers with more NaCl in between the pieces, stored for

a salting or curing period, and then dried (using sunlight or artificial indoor drying chambers). The salting period depends on several factors including the desired ripened characteristics in fish, the fish species, the amount of salt used, and the storage temperature. For example, increasing the amount of NaCl reduces the required time of storage.

Use of salt in fish preservation is not limited to dry application. Salt is an important additive in the preparation of fermented, pickled, or processed fish or fish products. In the making of fermented fish, known concentrations of salt are added to promote degradation of proteins and retard the growth of undesirable, putrefactive microorganisms. Also, this allows desirable, NaCl-tolerant (halotolerant), fermentative species such as lactic acid bacteria to grow. Pickled fish are marinated in salt brine or brine containing vinegar. Curing salt (containing sodium nitrate,  $\text{NO}_3$ ) can be added to the pickle to delay spoilage and control microbial activity during storage (Pederson and Meyland). Other ingredients—spices, sugar, herbs, or vinegar—are incorporated during the process to impart a particular flavor, texture, or color. Herring, haddock, and anchovies are fish species often available in the market in pickled form.

In manufacturing processed fish products, adding certain amounts of NaCl assists in the extraction of salt-soluble proteins and the formation of a sticky paste of fish meat. The development of the gelled paste might be due to the formation of a protein network structure or polymerization of myosin-heavy chains (Kumazawa, Numazawa, Seguro, and Motoki). In breaded processed fish products, NaCl is used in the predusting step to enhance adhesion of the batter to the fish (Claus, Jhung-Won, and Flick). Processing fish has created a niche market for products that otherwise would have been

wasted because of overharvesting of species, low consumer appeal, high processing costs, or limited shelf life.

### Salt, Spoilage, and Preservation

Over the years, a number of spoilage and pathogenic microorganisms, including lactic acid bacteria, *Pseudomonas* spp., *Staphylococcus* spp., *Salmonella* spp., *Clostridium perfringens*, *Clostridium botulinum*, *Escherichia coli* O157:H7, and *Listeria monocytogenes*, have been associated with fish and fish products. At certain concentrations, salt was found to prevent growth of many microorganisms by exerting a drying effect on microbial cells and tissue, which concentrates solutes in them, creating an environment unsuitable for microbial proliferation. Because some halotolerant or halophilic (salt-loving) microorganisms are not affected by salt, additional treatments such as drying, heating, curing, or smoking are helpful in controlling them. Dry-salted fish (that is, dried by the salting method), for example, are dried and/or smoked to extend their shelf life.

In addition to microbial spoilage, fish that contains high levels of lipids—salmon, herrings, and mackerel—are prone to oxidation and become rancid as microbial spoilage occurs (Jay). Because of their unsaturated nature, fish body oils are susceptible to oxidation and also easily develop rancid and unacceptable odors and flavors during storage (Waterman). Once fatty compounds are oxidized, the breakdown products of lipid oxidation potentially can react with proteins and vitamins, leading to a loss of nutritional value and quality of the fish (Pokorny). Salted sun-dried fish are more prone to oxidation than fish preserved by other methods because of their exposure to light and oxygen (Smith and Hole). Use of crude NaCl (which contains impurities such as chlorides, sulfates, calcium, and heavy metals) accelerates lipid oxidation during fish processing and will adversely affect the overall quality of the finished product (Yankah et al.).

In order to reduce the adverse effects of NaCl on lipid oxidation, color, and flavor of fish, fish and fish products are handled, prepared, and processed under refrigerated temperatures. Low temperatures reduce the rates of oxidative reactions and retard microbial growth. Products also can be vacuum packaged after drying and/or cold or hot smoking. Vacuum packaging creates an environment that virtually lacks oxygen, a promoter of oxidative rancidity. Chelating agents, bio-preservatives, antioxidants, and other compounds also can be added to maintain color, flavor, and integrity of the products.

Throughout history NaCl has been a popular and important food additive. The many advantageous properties that NaCl possesses led to its incorporation in several unprocessed and processed foods. Its functionality as a preservative, catalyst in extraction of NaCl-soluble proteins (binder), flavor enhancer, and color developer has played a major role in food processing and preparation. Improvements and advancements in technology worldwide have allowed even better use of NaCl by the food

industry, such as production of processed fish products. Because salt does have its limitations and disadvantages, its utilization conditions must be optimized to provide safe food for consumers, at the same time addressing their needs and concerns.

**FISH, SMOKED.** Wind-drying is the most ancient and basic way of preserving fish. Add the discovery of fire, and early humans might have found that fish hung up over a fire dried more quickly, and that, if the fire was

Worker preparing smoked bonito at a fish smoking establishment in Miyazaki, Kyushu, Japan. © MICHAEL S. YAMASHITA/CORBIS.

smoky, fish would acquire a different flavor and keep better. Indeed Cutting (1955) suggests that people might have begun to smoke fish deliberately in the Neolithic. However, it seems to be uncertain whether such smoking of fish was carried out later on, in ancient Egypt or classical Greece and Rome.

As Sue Shephard (2000) points out, archaeologists have uncovered the remains of what was evidently a substantial fish-smoking “factory” in Poland, dating back to the seventh century. And it is clear that European use of the technique was greatly expanded, perhaps mainly in order to deal with gluts of herring, in the medieval period. Dedicated smoke houses used for this purpose were in common use in England, and no doubt elsewhere in the fourteenth century.

Smoke is highly complex, having a couple of hundred or more constituents. So what it does to fish is also complex, but can be summarized by saying that it deposits on the fish various phenols, aldehydes, tars, etc. and that the combined effect of some of these, which have bactericidal properties, is to make the fish keep noticeably better.

In modern times progress has been made in the construction of special ovens for smoking fish; in analyzing

the constituents of smoke which are responsible for changes of flavor; in the choice of wood shavings or chips whose smoke produces the best results; and in elaborating the techniques of both hot and cold smoking.

Hot smoking was developed in northern Europe in medieval times. In this process the smoke temperature is very high and the fish is wholly or partly cooked by being smoked. Herring which were hot smoked on the northern coast of Germany were known as *Bücklinge*, which became “buckling” in English, but the process was also used for many other species of fish. The hot smoking of fish is also common in Africa. For example, a kind of shad is hot smoked in Ghana in primitive kilns made from oil drums. Hot smoked fish is succulent and tasty but in general does not travel or keep as well as cold smoked. Cold smoking, on the other hand, is not a cooking process; it consists simply in hanging fish in smoke (which may of course be slightly warm, but that is irrelevant), and the result keeps well.

As for the choice of combustible, the traditional preference in Britain was for oak, with ash as second choice and peat being used until recently in Scotland, especially for domestic smoking in their kitchen chimneys by fishermen’s wives. In Russia, the woods used have included

## HADDOCK

Since haddock does not take salt as well as cod, the traditional ways of curing haddock were by drying and smoking. In the category of smoked haddock the most famous have been what was originally a product of the fishing village of Findon, near Aberdeen in Scotland. Peat was used as the source of heat and smoke, and the haddocks, when sold, proudly bore the name Finnan haddocks or Finnan haddies. The taste spread to France where the product became so popular that in French the term "haddock" means 'smoked haddock', one significant instance of an English word invading the French language (which does of course possess its own word for fresh haddock, *églefín*). The taste also spread to the United States in the nineteenth century, witness the statement by G. Brown Goode and his associates (see bibliography) that smoked haddock were even then being manufactured in large quantities in Portland and Boston. It is interesting that Goode called them Finland haddocks, perhaps reflecting a misunderstanding of the true name by the American manufacturers.

The production of Finnan haddocks or the like no longer involves the use of peat and is carried out in many places. However, the essential process still involves the traditional stages. The fish, cleaned and split open, are left in brine for a while and then hung up to drain. As the surface dries, it develops an attractive gloss. Smoking comes next and is normally continued until the fish have taken on a straw color (which will darken further after the fish have been taken out of the smoking plant). Small haddock which have been treated in this way but withdrawn from the smoking process while their color is a very pale straw are known as Glasgow pales. This light coloration is at the opposite extreme from the lurid yellow hue often imparted artificially to the fish by large-scale commercial smokers.

Hot smoking is used for what are called Arbroath smokies. Arbroath is the Scottish town where their production became a local industry.

alder, oak, poplar, and lime. Wood from coniferous trees has also been used, but imparts a resinous flavor.

Nowadays there are numerous books on home smoking, explaining how various small contraptions can be used to produce smoked fish; and a few books which treat the subject in a general and historical manner, while not neglecting technical aspects. In this last category falls the

book by Cutting and that by Burgess and others (including Cutting, 1965). Zaitsev and others (1969), in their 700-page manual *Fish Curing and Processing*, are also helpful on the technical aspects. Sea fish smoked in Russia include sturgeon, cod, herring, whitefish and grey mullet. Freshwater fish include carp, bream, and pike-perch.

In modern times, the best known smoked fish is smoked salmon, now prepared in many countries and figuring on innumerable restaurant menus around the world. Many of the salmon which are smoked are farmed salmon, but the proportion of farmed to wild varies greatly. In North America more than half of the smoked salmon are farmed, most coming from British Columbia, but even so smoked wild salmon is much easier to obtain there than in Europe. Traditions of smoking salmon in the Pacific Northwest go back a long way, and Shephard has an interesting passage about the cultural significance which American Indians attached to these fish, believing them to be "undersea people who put on salmon skins to swim ashore and offer themselves as food."

Smoked eel, of which the best comes from the Netherlands, is now being produced in the United States, in Scotland, and elsewhere; and smoked mackerel has become a success internationally. These are all fish with a relatively high oil content, a feature which works well with smoking. However, less oily fish such as cod and haddock are also smoked successfully. In Britain there is a long tradition of smoking haddock.

Despite the ubiquity of smoked salmon and the importance of smoked haddock, many people in Britain regard the kipper, a form of smoked herring, as their top favorite. It dates back only to the 1840s, the period when railways began to facilitate rapid transport of cured fish from the ports to other areas, and soon achieved prominence because it was so useful in helping to conserve the huge catches of herring which used to be made off British coasts.

In North America, smoking has been used for more and more species, both freshwater (e.g., trout, also a highly popular smoked fish in Europe) and marine. Whitefish, marlin and tuna are examples of larger fish which have to be smoked in fillets. Swordfish is another large fish of global distribution that is smoked in many of the countries where it is caught. Halibut may be smoked, indeed this treatment seems to be the best way of dealing with Greenland halibut, a delicacy in Denmark.

In Asia, much of the smoking of fish is carried out on an artisanal small-scale basis, and the number of species involved is large. Smoked snapper (for example *pla kaphong* in Thailand) is excellent. In China, especially in the south, smoked pomfret is an important delicacy.

It is not only whole fish or fillets of fish which are smoked. Smoked cod roe is a prominent example of other parts being so treated. In Greece, imported smoked cod roe has largely replaced the dried roe of grey mullet as

the basis for the delicious fish roe paste known internationally as *taramosaláta*.

The indications are that the list of smoked fish and smoked fish products will be progressively extended, since most fish are susceptible to smoking and smoked fish, with smoked salmon in the vanguard, has been winning greater and greater consumer acceptance. In times gone by, smoking fish was done to preserve it. Nowadays there is a further, gastronomic, reason. The flavor of smoked fish has come to be appreciated in its own right. If the proportion of the global catch of sea fish which is smoked goes up, that should be viewed as a favorable development. It should lead to less waste, greater flexibility in the use of fish, and often more pleasure for the consumer.

**FISH AND CHIPS.** Fish and chips has a strong historic claim to the status of the national dish of industrial Britain. Perhaps fittingly, in postindustrial and postcolonial times it has been hit hard by competition from a proliferating variety of ethnic restaurants and takeout restaurants, especially Indian and Chinese, and by the rising cost of the traditional fish species to which its loyal adherents are firmly attached. Its origins coincided with the sustained rise in working-class purchasing power that was ushered in by falling prices in the last quarter of the nineteenth century. Although the identity of the first fish and chip shop cannot be confirmed, it was either in London's East End or in the textile factory districts of northern England, and it opened in about 1870, combining two commodities, fish fried in batter and chipped potatoes, which had previously been hawked through the streets as separate entities. It was a cheap and filling dish, enlivened with salt and vinegar, and it began as a late-night snack for revellers on the way home after the pubs had closed. By the turn of the century, however, the fish and chip shop had become a general feature of the urban industrial landscape, selling to women and families as well as to men, and to factory workers (and housewives) in the midday break as well as in the early evening and at night.

By 1910 there were about 25,000 fish and chip businesses in Britain, almost all of them single-family oper-

Fish and chips are a great favorite in Britain, although the health implications from eating this kind of fried food are much debated by nutritionists and physicians. This queue is eagerly awaiting lunch in Derbyshire, England. © ROBERT HOLMES/CORBIS.

ations (the success of the Harry Ramsden chain in the late twentieth century was novel and anomalous). By 1927, as the industry reached its peak, there were perhaps 35,000. Fish and chips provided the dominant market for the catches of the steam trawler fleets that were rapidly expanding at the turn of the century. The business also consumed huge quantities of potatoes and generated a major specialized engineering industry to supply frying ranges and related products. It was both mocked and celebrated in music-hall song, and different British regions took pride in their own preferred species and specialties, especially "jumbo haddock" fried in beef dripping in the coal-mining and woollen-manufacturing districts of West Yorkshire.

As a labor-saving foodstuff, prepared outside the home and often defying the "civilising process" by being sold in newspaper wrapping and eaten in the street with the fingers, fish and chips attracted a lot of snobbish and pseudo-scientific criticism. Social reformers associated it with slovenly domestic habits and claimed that it was expensive, while local government medical officers alleged that it spread illnesses, and in many towns it was regulated as an "offensive trade" alongside soap boiling and rag picking. In Scotland, where many of the fish friers were Italian immigrants, authority was particularly suspicious. But the balance of the evidence suggests that it provided a valuable and palatable boost to working-class diets, while taking some of the strain off hard-working domestic labor and providing an outlet for aspiring petty capitalists in working-class communities. It was even claimed that fish and chips played an important part in winning World War I by sustaining morale and stamina on the home front, and by the 1930s it was becoming increasingly acceptable to middle-class consumers, although by that time it was beginning a long, slow decline that still continues at the turn of the millennium.

**FISHER, M. F. K.** Mary Frances Kennedy Fisher (1908–1992) wrote twenty-three books and hundreds of articles in which cuisine was virtually always her metaphor of choice. Many of her works included recipes, and she is often characterized as a food writer; this description, however, underestimates her powers as a highly creative author and a keen observer. She wrote of human hungers in the deepest sense. Fisher recognized the rich psychological, social, and cultural meaning of cuisine, identifying food, security, and love as fundamental and intertwined needs. Memorable meals eaten, rich wines and liqueurs imbibed, and the company she kept are equally important in her often highly personalized writing.

Mary Frances Kennedy Fisher at home in Sonoma, California, 1971. © AP/WIDE WORLD PHOTOS.

Born in Albion, Michigan, but raised in Whittier, California, from the age of four, Mary Frances Kennedy was the eldest of four children. At the age of nine she began experimenting in the kitchen and preparing meals. She wrote that food preparation brought recognition from her family, as well as proof of her own ontological being. Her father, Rex Kennedy, owned and published the local newspaper. Whittier was a conservative Quaker town, and the Kennedys, Episcopalian. Their religion prevented their complete assimilation into the community; thus, Mary Frances grew up with a perspective akin to an ethnographer: never fully part of the local culture, but with a defined role to play in it. She developed a discerning eye and used it to interpret others' lives while remaining removed from them.

At age twenty-one, the author married Alfred Young Fisher, the first of her three husbands. He received a graduate fellowship to study in France, and Mary Frances accompanied him, choosing to study art at the University of Dijon. The next three years proved formative as she became fluent in French and was introduced to regional cuisines. Although she was not to consider herself a writer for some years, she was a passionate correspondent throughout her life. Her expertise as a wordsmith was already apparent in her letters home from France (Barr et al., 1997).

Fisher's permanent home was California, but she passed numerous extended periods in France. Her writing reflects these distinct parts of the world. She also owned a home and a vineyard in Switzerland with her second husband, Dillwyn Parrish. She frequently wrote of her trans-Atlantic journeys by ocean liner and train travels within Europe. These accounts included descriptions of dining rooms and dining cars, the cuisine, its preparation, and its service. The journeys became symbolic of transitions in her life, as in one of her most compelling works, *The Gastronomical Me* (1943).

Fisher wrote in a broad range of genres including fiction, nonfiction, journalism, screenplay, poetry, and children's literature. Although her writing includes two novels, she excelled at essays. While many of her writings were based on events in her own life, she fictionalized these first-person narratives, transcending the boundaries of autobiography.

Fisher had a bold character; she was strikingly independent and she spun a worldly mystique around her tales. After divorcing Donald Friede, her third husband, she raised two daughters as a single parent. Her worldly panache convinced many readers that she was wealthy. In reality, her commitment to writing meant that she often struggled to make ends meet, earning less from her books than her published essays, which included a two-year series for the *New Yorker*, compiled afterward in *With Bold Knife and Fork*.

Among Fisher's greatest contributions was the translation of Jean Anthelme Brillat-Savarin's *The Physiology of*

*Taste*. The early-nineteenth-century book of French manners is a masterpiece of droll commentary. Fisher's achievement lies not only in a masterful translation, but in her witty notations, equal to Brillat-Savarin's original, self-effacing, humorous style.

Fisher generously mentored young writers and had significant impact on Jeannette Ferrary and Anne Lamott. She was a close friend of both James Beard and Julia Child; the three visited, corresponded, and influenced one another. She advised and befriended restaurateurs including Alice Waters of Chez Panisse in Berkeley, California. Fisher favored fresh and local foods; she called them honest. Her approach had a significant impact on the evolution of California cuisine in the last quarter of the twentieth century. She passed her last years in the California wine country, and the region became the subject of some of her work.

W. H. Auden stated that had M. F. K. Fisher's subject been anything other than food, she would have been appreciated as the United States's finest twentieth-century author. Her books were widely translated and repeatedly republished. She made French cuisine and culture accessible, opening the doors of western European gastronomy to North Americans and other readers worldwide; her work reflects the sense of place she felt on two continents. Fisher received numerous literary prizes, including a lifetime achievement award from the James Beard Foundation. She was elected to the American Academy of Arts and Sciences in 1991.

**FISHING.** Fishing is the art and science of catching animals that live in water. This pursuit can be for fun or profit. Recreational angling is often practiced as an art, with little to no expectation of actually catching and keeping a fish for personal use. In commercial fishing, there

This rare manual on fishing called "The Excellent Little Fish Book" was published anonymously in Nürnberg about 1660. Parts of the text are based on Georg Mangolt's *Fischbuoch* [Fish Book] printed in Zurich in 1557, one of the first books to deal with fishing as an art and as a sport. ROUGHWOOD COLLECTION.

is an expectation of catching and keeping fish or invertebrates and an expectation of selling those animals for profit. This article will focus on commercial fishing.

Hunting and gathering animals that live in water is an ancient form of food gathering. Today, aquatic animals caught from wild populations are one of, if not the last, major food category we still predominantly hunt and gather. Virtually all of the other foods we consume are grown in agricultural operations. However, we are in the early phases of a major transition from hunting and gathering fish and shellfish to agricultural production (aquaculture) of aquatic animals.

We live on a wet planet. Water comprises greater than 70 percent of Earth, and that habitat is home to far more vertebrates than the dry portion of the planet. Given the size and scope of aquatic habitats and the diversity of species present, it is not surprising that it took

until 1989 to reach maximum sustainable yield from the world's oceans. Maximum sustainable yield is the tonnage of aquatic animals that can be harvested annually while maintaining healthy populations. It is important to note that there are two distinct groupings when discussing fish: individual species and the sum of all species. Further subdivisions are possible, but the important point is that individual populations or species can be in poor condition (for example, low numbers) while overall, fishes in that body of water are generally healthy.

Since 1989, global commercial harvest has been close to 90 million metric tons, and that figure is not expected to increase. The largest commercial harvest industries are for species used for making fish meal (anchovy, herring, and menhaden) and those used for food (pollack, mackerel, and capelin). The largest species-oriented industries are listed in Table 1.

There are over 22,000 species of fish, and the United Nations Food and Agriculture Organization monitors commercial harvest of slightly over 1,100 species. Further, a thorough understanding of fish taxonomy (the science of fish identification) is not commonplace among many commercial fishermen. Thus, many species simply are grouped into a nonspecific category such as marine fishes. From the data above, it seems clear that the commercial fishing fleets from the western coast of South America (Chile and Peru) and Southeast Asia (China, Thailand, Vietnam, Myanmar, and Japan) harvest more fish than other parts of the planet. Not shown in Table 1 are the most productive fishing grounds, which are the

Pacific Northwest, Pacific Southeast, and the northeastern portion of the Atlantic Ocean.

There are several reasons postulated for the plateauing of commercial harvests. Pollution and other environmental stressors on fish populations are common speculations, as well as overharvest by commercial fishing fleets. From the industrial revolution to current times, pollutant levels in the oceans increased and certainly had some negative impact on populations of animals in aquatic habitats. Over the same time period, commercial harvesting equipment improved significantly and also contributed to declines in populations and leveling of harvest volumes. Regardless of the cause, wild populations of many fish and shellfish declined in the latter half of the twentieth century. However, it is important to grasp the scope of the situation before assigning blame to any particular cause.

The average depth of oceans is over 13,000 feet (4,000 meters). Over 84 percent of the oceans are deeper than 6,500 feet (2,000 meters). The Marianas Trench in the western Pacific Ocean is the deepest place at 36,000 feet (11,000 meters), deeper by a mile than the altitude of Mount Everest (29,000 feet, or 8,845 meters high). As stated earlier, the vast majority of our planet is under water. Many species of fish either travel long distances in their normal habits or the populations inhabit large areas. Given these facts, establishing accurate population estimates is virtually impossible. Fishing gears and efficiency of commercial harvest have increased significantly and also contribute to attaining maximum sustainable yield.

Fishing gears are largely unchanged from ancient times. Nets of various types are the most commonly used commercial fishing gear. The basic concept of a net, regardless of the configuration, is the same today as it was when ancient man first wove fibers together to make nets. Impaling devices such as spears and harpoons are also unchanged from ancient times. There are numerous types of traps in use, mainly for trapping crustaceans (lobsters, crabs, crayfish), and those have ancient origins. Fishing gears have become more efficient, but in subtle ways. Prior to about 1980, trawls (nets pulled behind a boat) could attain only a limited depth and were nonspecific in their catch. Significant research efforts resulted in trawls that could be fished deeper (up to 8,200 feet, or 2,500 meters) and had devices that would tend to exclude mammals or turtles. Harpoons are not routinely used in the twenty-first century, and spears have evolved to spear guns for individual fishermen. Trap materials have changed with the advent of polymers, but the basic configurations have not changed for hundreds of years. The major change that occurred is not in gears, but in the boats.

Commercial fishing boats are capable of staying at sea for months at a time, giving fishermen the ability to fish anywhere in the world. Technological advances in

engines, fuels, and boat designs, coupled with international treaties that allow foreign fishing fleets safe harbor, increased the efficiency of commercial operations. Harvested animals can be cleaned on board and frozen at  $-76^{\circ}\text{F}$  ( $-60^{\circ}\text{C}$ ) for extended storage. Large companies evolved to more efficiently harvest fish, and those companies developed the concept of multiple fishing boats and a mother ship for processing and storing fish. It is not uncommon to find Japanese fishermen in the North Atlantic Ocean harvesting giant bluefin tuna. Fishermen also take advantage of the other forms of commercial transport, taking some of their harvest to nearby ports and consigning them to air freight companies for transport back to home bases. Frozen giant bluefin tuna are flown from New York to Tokyo regularly.

Restrictions on commercial harvest have been common since the early 1980s. As populations declined, state or federal regulatory agencies restricted harvest by establishing quotas (limited number of fishing licenses), restricting harvest volume (limitation on volume, which can be expressed per day, week, or season), or restricting gears (numbers of traps, length of nets, number of nets). There is at least one example on every coast of the United States in which commercial harvest has been significantly cur-

tailed, even to the point of declaring the species rare and endangered. However, as mentioned above, the size and scope of fishing demands that many countries contribute toward management of populations.

International agreements are in place that define who can fish where, seasons for fishing, and gear acceptance. Most countries claim some distance from their shores as available only to local fishermen. The Fisheries Conservation and Management Act (or the Magnuson Act) was adopted in 1976 and declared the first two hundred miles (322 kilometers) from U.S. shores as open only to U.S. fishermen. The International Whaling Commission was established in 1946 to regulate the global harvest of whales, but has only slowly gained momentum and has no real authority to enforce agreements. Native Americans retained many of their rights to traditional fisheries and harvest those populations in the twenty-first century. Many times, these harvests are contrary to recommendations from regulatory agencies and are controversial with other fishermen.

Fishing communities in New England, the Gulf Coast, and the West Coast have been seriously impacted by the decline in commercial fishing. Whole communities are in significant economic crisis. New industries are

not readily apparent for a labor force trained in commercial fishing, processing, and distribution of fish and shellfish. Since the 1980s the fisheries have been in sharp decline, and with it a way of life. Some fishermen, with modified gears, are able to switch species. For example, in 1970, the harvest of the Argentine shortfin squid was 1,300 metric tons. However, harvest of anchovy became erratic and new species were sought, including the shortfin squid. Between 1970 and 1999, total harvest of the Peruvian anchovy by all countries varied from 93,000 metric tons to over 13 million metric tons. Over this same time period, harvest of the shortfin squid increased to just over 1 million metric tons. Harvest of the Atlantic cod, the species used in most fish sandwiches in the United States, has declined from over 3 million metric tons to around 1 million metric tons. A replacement has not been identified in the North Atlantic ocean. Creative marketing techniques also opened opportunities for commercial fishermen. A deep-water species around Australia, New Zealand, and Tasmania was once unmarketable. The local name for this fish was the slime head. However, under its new name, orange roughy has found a ready market in the United States.

The newest of the commercial harvest industries developed in the past forty or fifty years and focused on species inhabiting coral reefs. The pet or hobby aquarium trade increased significantly as technology made it possible to maintain saltwater fish tanks in any temperature-controlled room. Harvest was often by hand, using small dip nets, but more recently other forms of harvest have been used, including poisons (cyanide) and explosives. These collection methods are indiscriminate and have been banned in most countries. The demand for ornamental fishes coupled with the gradual bans on many harvest techniques led to development of aquaculture industries focused on tropical fishes for home aquaria. The same scenario is occurring with fishes destined for food. However, culture of fishes for making fish meal is not occurring and appears unlikely. Fish harvested for fish meal do not command high prices and need large areas. The economics of that form of aquaculture are not favorable.

**FLOWERS.** Throughout history, flowers, like seeds, leaves, and stems, have contributed to human cookery. But edible flowers, when added to food, provide more than sustenance and flavoring. They add form and color. They are an exception to the rule, a spark of interest, and a spectacle that cannot last. Whole fresh flowers connect people to food in a way that nothing else does. Just as beauty is associated with good in children's fairy tales, so too with food: flowers add to the pleasure of eating. Flowers have long been an essential link in the human food chain. The joining of flower pollen with flower ovules is a starting point in the cycle of life. More than we imagine, life depends on a sequence that starts with flowers and progresses to pollination, seeds, and plants. Without the rebirth of plants, without continuous replacement, life would cease to exist. To sustain life, there must be birth and growth.

#### Flower Biology

Flowers are the blossoms of plants and the reproductive organs of angiosperms. Edible and nonedible flowers alike have a common concentric structure of distinct parts that, beginning at the base of the flower and proceeding up to the center, include the stem, ovary, sepal, petal, stamen (filament and anther), and pistil (style and stigma).

Flowers have been used in cookery for centuries. Here, flowers offer a touch of exotic color and texture to a salad garnished with pansies and nasturtiums. PHOTO BY ANDRÉ BARANOWSKI.

Flowers also figure as a flavoring in cookery, from violet syrup to rosewater, which was popular in both Byzantine and Arabic cookery. Rosewater still plays an important role in the cookery of many Eastern Mediterranean countries. In this 1838 engraving, a vendor is shown selling rosewater in Istanbul. His still is on the left. ROUGHWOOD COLLECTION.

Flower petals are showy, fragrant, and often fully flavored. Sepals, on the other hand, are leaflike structures that enclose the flower before it blooms and, unlike petals, are not valued as a source of food, flavor, or color. Stamens are the male parts, and they produce pollen. Anther sacs hold pollen, and in the case of pine trees, so much pollen is produced in the early spring that it accumulates in masses on lake shorelines and can be scooped up, dried, and used as an ingredient in bread and soups. Pollen is a complete food, rich in proteins, carbohydrates, vitamins, minerals, and enzymes. It can tone, detoxify, and balance the human organism.

Pistils are the female flower part. When pollen grains light on pistils, they absorb moisture, grow tubes, penetrate ovaries, and, finally, connect to ovules to fertilize seeds. Flower nectaries, or nectar glands, secrete nectar, which is used by bees to form honey. Nectar glands are located at the base of the ovary and above the anther.

## History

In Roman times rose petals were used to flavor cooked brains, sweet marjoram flowers were baked in hash, and safflower petals were used for a boiled sauce. Roses and violets were added to wine to enhance flavor.

Later, in the Middle Ages, rose petals were used to flavor cakes, creams, and confectionery. Both orange blossom and rose petal water are flavorings made from flowers. Since the third and fourth centuries C.E., rose water has been made by steeping petals and then distilling the water. Middle Eastern and Indian sweets such as

shola, baklava, firni, and halvah are flavored with rose water. It is also used to flavor Middle Eastern beverages such as lassi and sherbet. Flower use varies from culture to culture and age to age. While in America today roses are used more as a decoration than a flavoring, dried rosebuds are used as a condiment in Asian cookery.

## Symbolism and Healing

Flowers are a symbol of life and a source of birth and healing. For example, when placed on a wedding cake flowers signify new life, and at times of sickness and death they comfort the grieving. During the Easter season the passionflower is a symbol of the holy passion, the suffering of Jesus Christ. In ancient Greece the rose symbolized love, beauty, and happiness, and during the Roman era, roses were associated with Venus, the goddess of love.

Edible flowers are used with various foods to mark events such as graduation, marriage, and retirement. Christians associate flowers with Christmas, Easter, Ascension, and Epiphany. States and nations have adopted flowers as emblems. For example, the emblem of the Netherlands is the edible tulip, and Illinois, New Jersey, Rhode Island, and Wisconsin have adopted the violet as their state flower. Four states—Georgia, Iowa, New York, and North Dakota—have adopted roses. Florida adopted the orange blossom, and Hawaii the hibiscus.

But in addition to their symbolic and spiritual uses, flowers are consumed for their healing properties. Flowers from the great scarlet poppy contain alkaloids such as thebaine, which is a source of codeine. The unripe pods

## POPULAR GARDEN FLOWERS AND THEIR FLAVORS

- ANISE HYSSOP: sweet, anise, or licorice; used to flavor red meats and as an herb
- CARNATION: mild to sweet; use petals only in salads
- CHIVE: onion smell, peppery, savory; use as garnish, flavoring for meats, salads, sauces
- CHRYSANTHEMUM: savory, mild to strong, and bitter (some are poisonous)
- DAISY: sweet and savory; flower buds are pickled, flowers used on salads, used to make wine
- DANDELION: savory; a bitter herb mentioned in the Old Testament: used in salads and wine, the greens are eaten as a vegetable and sold canned
- DAY LILY: savory (can be toxic)
- FUCHSIA: mild flavor; use whole as garnish on salads and cooked fish
- GRAPE HYACINTH: grape flavor, slightly sour, bitter aftertaste (can be toxic)
- HOLLYHOCK: mild; use as garnish or container (can be toxic)
- HIBISCUS: slightly acidic, sweet; used in tropical fruit salads
- HONEYSUCKLE: sweet; use in salads and with fish
- LILAC: strong smell; sweet and savory; crystallize the flowers to use on cakes or confectionary; used in tea blends
- MARIGOLD: savory; small four- and five-petal varieties best; use in soups
- NASTURTIUM: savory, peppery, piquant, like watercress; used in salads and used fresh as a garnish for hot vegetables
- PANSY: sweet and savory; crystallized to use on cakes; used fresh on salads
- POPPY, EUROPEAN AND CALIFORNIA: mild; use in salads for color
- RED CLOVER: mild, like hay; used with wild herb salads; add florets to salads
- ROSE: sweet to bitter; herbal teas; use old varieties; also used to decorate cold platters of meat and fish
- ROSE PETALS: sweet to bitter, crystallize; add to salads; garnish plates
- SCENTED GERANIUM: tastes like variety, either lemon or rose used to make tea and an herb in pastry
- SQUASH: savory; batter and fry into fritters; serve as vegetable; also served stuffed
- SUNFLOWER: member of daisy family; use unopened flowers like artichokes or use the bitter petals; garnish for granola made with sunflower seeds; use with pasta salads
- TULIP: mild, sweet to bitter; use with asparagus or rhubarb
- VIOLET: sweet; use in salad, as a garnish for poke salad, an egg dish that includes cooked poke; use crystallized on cakes

of opium poppies are used to make many alkaloids including morphine, thebaine, narcotine, and codeine. The list of flowers used as medicine is extensive, and it includes arnica used as an anti-inflammatory analgesic and hawthorn used as an antispasmodic, cardiac, and vasodilator. The marsh mallow is a diuretic, antitussive, and demulcent. Passionflowers are a sedative. Rosemary is used as a tonic, diaphoretic, antiseptic, and astringent. And finally, due to their astringent qualities, some flowers, including nasturtiums, roses, and yarrow, are used as bath oils.

### Preparation and Consumption

While flowers are often used fresh, they are also preserved for later use when they are stored dried, freeze-dried, candied, crystallized, or even frozen in ice cubes.

Flowers or flower parts are eaten as sweeteners, vegetables, flavorings, beverages, and garnishes. In terms of quantity, the most widely used flower today is the hop, a conelike flower or strobilus that is dried and used to flavor beer and ale and is also an antimicrobial

agent. Squash blossoms are served stuffed, fried, or deep-fried. The great variety of flower foods is typified in honey, a sweetener made by bees from flower nectar. Cauliflower, broccoli, and pickled capers are flower buds. Pansy and lilac flowers are crystallized and then used for cake, cookie, and pastry decorations. Lavender, chamomile, lilac, and jasmine flowers are used to make herbal teas. Hibiscus flowers are boiled and sweetened to become *agua de jamaica* or jamaica water, a Mexican beverage made like tea, but served like iced tea or fruit juice. Violets, mimosa, and forget-me-nots are used to flavor confectionery.

Today, out-of-season blossoms, as well as dried flowers and flowers made of marzipan and frosting, are common on wedding and birthday cakes. Flowers are stored and shipped fresh, pressed, dried, and crystallized. Some institutions even use flowers of plastic, silk, paper, wood shavings, and wire to decorate food. This pursuit of flowers is epitomized by upscale restaurant chefs who order a box of mixed fresh flowers, and then use them indiscriminately, either whole or in parts, as the finishing

touch to elegantly served dishes from medallions of venison to creamy custards with Grand Marnier.

The stigmata of the fall-blooming saffron crocus provide an essential spice for the bouillabaisse of southern France, the paella of Spain, the risotto of Italy, and the pilaf and biryani of India. Saffron, which is native to Asia Minor, adds an orange-yellow color to these dishes and gives them a spicy, pungent, and bitter flavor. Today, some of the finest saffron is produced in Spain. Saffron is costly because it must be handpicked; it takes four thousand stigmata to yield one ounce of powdered saffron.

### Issues

The use of edible flowers as food also raises a number of concerns. First, culinary flowers must be free from insecticides and herbicides. In one sense, assuring toxin-free flowers is easy because fresh flower buds and flowers grow quickly. On some plants it takes only a few days for new buds and flowers to form. On the other hand, commercial flowers are often sprayed to keep them pest-free and visually attractive.

But of even greater concern than pesticides is the loss of historical species. As a result of evolution and environmental degradation, there has been a loss of species and genetic diversity. This, however, is somewhat offset by natural evolution and, in the case of flowers, the constant breeding of new and more beautiful varieties. A third problem is the use of personal or regional nomenclature that makes it difficult to trace the use of flowers in history. Cultures from Native Americans to tribal Africans have celebrated food with flowers, but these traditions are largely lost.

**FLUORIDE.** Fluoride is an important trace element in human nutrition. Daily exposure to small quantities is

widely considered to be vital for maintenance of sound tooth structure. Ingested or systemic fluoride has long been known to offer significant benefit when supplied during tooth formation in childhood. More recently, topical exposure (that is, making fluoride available at the tooth surface) has been shown to provide benefits throughout life, even for older adults.

### Sources of Fluoride

Water, rocks, soil, and living tissue all have naturally occurring fluoride as a constituent. Crystalline and carbonate minerals containing fluoride are common throughout the earth's near-surface crust. As water flows through the environment, fluoride and many other ions dissolve from sedimentary rock layers and soil into aquifers, streams, rivers, and oceans. Dissolved ions are essential for humans and all living things. Fluoride ions are absorbed directly from the water we drink.

### Fluoride in Bone and Tooth Tissue

Fluoride ions taken systemically can become incorporated within bone and tooth tissue. Although bones and teeth have an organic matrix, it is their inorganic or crystalline hydroxyapatite composition that gives them their strength and hardness. Living human cells use available calcium and other minerals to form strong hydroxyapatite matrices. When fluoride ions are also available to the cells, an additional material called fluorapatite is formed. Integration of a small amount of fluorapatite within a hydroxyapatite matrix may produce a more durable substance than is found with hydroxyapatite alone.

### Topical Mechanism

Fluoride ions can also provide a very strong surface or topical effect for teeth when available on a regular basis. One such effect is that topical fluoride inhibits the ability of some bacteria to produce dental plaque by blocking the function of important intracellular bacterial enzymes. Much more significantly, topical fluoride also leads to reduced demineralization and increased remineralization of enamel surfaces.

### Bacterial Acid and Chemical Balance

Demineralization of a tooth occurs when bacteria create an acidic or low pH environment at the tooth surface. The acidity dissolves hydroxyapatite, releasing positively charged calcium ions and negatively charged carbonate and phosphate ions into saliva. When normal saliva flow dilutes the acidity, the positive and negative ions recombine and remineralize the surface.

This cycle represents a balance. Diets rich in fermentable carbohydrates such as mono- and disaccharides, which are relatively simply sugars, disrupt the balance. They stimulate some oral bacteria to produce dental plaque and acid. Dental plaque is a substance that attaches to tooth enamel and is colonized by the bacteria that form

it. Once such a colony is established, each ingestion of fermentable carbohydrate causes approximately one half-hour of intense acid production by the bacteria. This burst of acid production lowers the pH near the tooth surface, demineralizing large amounts of hydroxyapatite. The balance is disrupted and, as the cycle is repeated, it damages the tooth's surface.

### **Topical Fluoride and Stronger Enamel**

When sufficient amounts of negatively charged fluoride ions are routinely present topically at the tooth surface, a different pattern emerges for this cycle. The balance of demineralization and remineralization actually builds fluoride into the tooth's surface structure. Over long exposure to fluoride in saliva, more and more fluoride is incorporated, and the enamel surface becomes stronger. A much greater increase in acidity is then necessary before a destructive imbalance in the cycle will be initiated. This surface or topical effect is thought to be the primary means by which fluoride prevents dental caries.

### **Benefits of Community Water Fluoridation**

In studies of many communities over several decades, it has become clear that there is great benefit to maintaining proper fluoride levels in the public water supply. A concerted public health effort throughout the decades since the 1950s has led to the maintenance of fluoride at these levels in many public water supplies.

Community water fluoridation is intended to provide fluoride at concentrations ranging from 0.7 to 1.2 ppm. Coincidentally, this is about the same concentration of fluoride that is found in ocean water. Levels are adjusted within this range regionally and throughout the year. This provides lower concentrations of fluoride when people are likely to drink more water and higher concentrations when less water consumption is expected.

Without other significant sources of fluoride during the 1950s and 1960s, community water fluoridation produced reductions of 40 to 50 percent in the number of cavities or dental caries among children. Their teeth had enamel that was more resistant to caries both when it was formed and throughout life.

Other countries have assessed a variety of alternative means for delivering protective levels of fluoride. These have included supplementation with tablets or drops, salt fluoridation, and milk fluoridation. However, in the United States, fluoridation of public water as part of purification treatment remains the most effective and economical means for providing this benefit to communities. Currently about 60 percent of the U.S. population has fluoride maintained at these levels in their drinking water.

In the 1980s, it became clear that the positive effects of water fluoridation were not limited to developing teeth. Studies of people age sixty-five and older showed that it was beneficial even when all of the fluoride expo-

sure took place after tooth eruption. Those who lived in communities with fluoridated water as adults had significantly lower rates of dental caries on exposed tooth root surfaces than comparable older adults without fluoridated water.

### **Fluoride and Osteoporosis**

There has been interest in potential positive effects of fluoride supplementation on increased bone density. When ingested, fluoride is absorbed primarily from the upper gastrointestinal tract and is excreted in urine. Fluoride that is not excreted is deposited in calcified tissues—bones and teeth.

Osteoporosis, loss of bone density, is an increasingly prevalent problem in the U.S. population among both men and women. Unfortunately, research to date does not suggest a useful effect of fluoride on bone strength, even when it is supplemented at concentrations twenty times greater than that found in fluoridated water.

### **Early Research on Fluoride**

It was research on the effects of prolonged intake of excessive amounts of naturally occurring fluoride that led scientists to understand the protection afforded by healthy fluoride levels. In the 1930s, a dentist in Colorado, Dr. Frederick McKay, became curious about a brown surface stain seen on some of his patients' teeth. These teeth often had a rough and porous surface texture, yet they were also far less prone to develop dental caries.

McKay's early observations led to a long series of investigations. It became clear that this problem, a severe form of fluorosis, resulted from very high levels of naturally occurring fluoride in drinking water. McKay's water samples had fluoride concentrations as much as fourteen times greater than that recommended today for community water systems. These investigations led to the discovery that when fluoride was present at the low levels that are now widely used, it offered powerful protection from dental caries without any adverse effects.

### **Reevaluation of Fluoride Use**

By the 1990s, the wide availability of fluoridated water led scientists to reevaluate fluoride use practices. Particular attention was paid to the potential for a diffuse exposure to fluoride throughout the population. Many packaged foods are processed in communities with fluoridated water, becoming sources of small amounts of fluoride to those who consume them. Far more important, however, is the use of toothpaste and other products containing fluoride. It was concluded that community water fluoridation levels remain appropriate, but that greater care must be taken in the use of fluoride toothpaste.

Levels of fluoride in treated drinking water are extremely low when compared to concentrations in common therapeutic products. For example, fluoride

concentration in over-the-counter fluoride mouth rinses is generally about 230 parts per million (ppm); toothpastes contain about 1,000 ppm; prescription home-use mouth rinses and home-use gels range from 1,000 to 5,000 ppm; professionally applied fluoride gels contain 10,000 to 12,300 ppm; and professionally applied fluoride varnishes contain about 22,000 ppm.

The additional sources of fluoride, primarily toothpaste, have led to lower rates of dental caries in U.S. communities not provided with fluoridated water. However, even with these lower background rates of dental caries in the population, it is estimated that community water fluoridation alone still provides an additional reduction of 20 to 40 percent in dental caries when comparison is made to caries rates for Americans who do not have fluoridated water but who use fluoride toothpaste.

### Fluoride Issues for the Future

During the reevaluation of fluoride in the 1990s, concerns were raised regarding the potential for fluorosis. In contemporary studies of fluorosis in the U.S. population, nearly all observed cases have been classified as "very mild" or "mild." These are categories of "white-spot" discoloration that are usually only apparent to a dentist conducting an intraoral examination. Ingestion of fluoride toothpaste is considered the primary explanation for these white-spot discolorations.

Children are likely to swallow toothpaste while brushing, ingesting an unintended and excessive amount of fluoride. The most effective strategy for avoiding mild fluorosis is to limit children to a pea-sized quantity of toothpaste at each brushing. This quantity is adequate for caries prevention and oral hygiene, but it should not lead to development of fluorosis.

Use of infant formula and some baby foods has also raised a degree of concern. Because of infants' very small body mass, the proper intake of systemic fluoride is lower than that for slightly older children. Some studies have identified varying levels of fluoride in these products, some approaching levels that are associated with increased risk for very mild or mild fluorosis in infants. Physicians and dentists are urged to use caution in prescribing fluoride supplements for infants and very young children living in communities without fluoridated water because they might be consuming these fluoride-containing products.

The U.S. Environmental Protection Agency has set a standard of 4.0 ppm as the maximum allowable fluoride level in drinking water. Within the United States, fluoride levels in drinking water are actually maintained at about one-fourth of this level. However, in some developing countries, particularly in southern Asia and northern Africa, natural fluoride is present at extremely high levels. In India, for example, a study sponsored by the World Health Organization found natural fluoride levels exceeding 1.5 ppm in about 8 percent of samples,

with some concentrations as high as 22.0 ppm. In such areas, public health workers actively engage in efforts to reduce fluoride exposure and eliminate fluorosis.

### Conclusion

Nearly one hundred organizations with related expertise, including the World Health Organization, the U.S. Public Health Service, the American Medical Association, the American Public Health Association, the American Society for Clinical Nutrition, the American Society for Nutritional Sciences, the International Association for Dental Research, the FDI World Dental Federation, and the American Cancer Society have recognized the importance of daily fluoride intake for dental health. Particularly when supplied through community water fluoridation, ensuring adequate dietary fluoride exposure has been an extremely safe and cost-effective public health measure. Fluoride is a trace element that has extremely important personal and public health benefits for promotion and maintenance of optimal oral health.

**FOLIC ACID.** Folic acid is a water-soluble B-vitamin first identified in 1930 by Wills and Mehta as "Wills factor." Wills factor cured the anemias of pregnant women in India, a clinical condition that commonly results from undernutrition. This vitamin was later isolated from spinach leaves and named folic acid (Latin *folium*, leaf). Unlike most bacteria and yeast, mammals cannot synthesize folate and, therefore, require folate in the diet. This vitamin is present in the body as a family of at least nine structurally related chemical compounds that are collectively referred to as folate. The term *folic acid* refers to a synthetic form of the vitamin. Folic acid, which is biologically inactive, is found in foods that have been fortified with it. Folic acid is also the form that is present in nutritional supplements. Folic acid can be converted by living cells to a biologically active form called tetrahydrofolate. This active form serves the same biological function as natural folates. The terms "folic acid" and "folate" are therefore often used interchangeably.

### Chemical Forms of Folate

The different forms of folate found in the body exist primarily as modified forms of tetrahydrofolate. Each tetrahydrofolate form differs by modification of the selected positions in the molecule that involve the placement of a single carbon unit. Additionally, folate derivatives found in cells contain a glutamate polypeptide tail that consists of two to eight glutamate residues in length. This polyglutamate chain is required for folates to perform their biochemical functions and also to retain folate in the cell. The glutamate chain prevents the molecule from crossing cell membranes.

### Dietary Folate

Vegetables are good dietary sources of naturally occurring folate, especially dark green leafy vegetables. Citrus fruits and fresh juices, berries, legumes, liver, and whole grains are other good sources. Most naturally occurring folates are sensitive to degradation by air and heat but are stabilized when bound to proteins present in foods. For this reason, fresh fruits and vegetables are the best sources of dietary folates since many food folates are de-

stroyed during food preparation. Dietary folates contain a polyglutamate chain that must be removed by digestive enzymes in the intestine. These enzymes leave a single glutamate residue on the folate, and the folate is then absorbed by the intestinal cell. Most folates are taken up by the liver, which is the primary storage site for folate. Folate can then be redistributed to other tissues from the liver. Glutamate chains are re-elongated by the body after the absorption of folates with single glutamates.

### Overview of Folate Metabolism

Folate serves as a cofactor that delivers single carbon units to particular enzymes that catalyze biochemical reactions. These folate-dependent biochemical reactions are referred to collectively as one-carbon metabolism. Folate functions in both the cytoplasm and mitochondria, the energy-producing units, of mammalian cells. Folate metabolism in mitochondria is responsible for the generation of formate, a source of one-carbon unit. Formate escapes the mitochondria and is a primary source of the single carbon units for one-carbon metabolism in the cytoplasm. One-carbon metabolism in the cytoplasm is required for the synthesis of DNA precursors, and the amino acid methionine from its precursor, homocysteine. Methionine, in turn, is converted to the cofactor S-adenosylmethionine or SAM. SAM serves as an additional source of single carbon units in the form of methyl groups that are required for other metabolic reactions including the methylation of DNA, RNA, and proteins. SAM also is required for the synthesis of phospholipids, neurotransmitters, and many small metabolites.

### Folate as a Therapeutic Target

Folate-dependent reactions are fundamental for DNA synthesis and maintenance of DNA integrity. Therefore, folate is required for cell growth and replication. It is not surprising that folate-dependent enzymes have proven to be effective targets for antitumor and antimicrobial drug therapies. These pharmaceutical agents are structurally similar to folate and are referred to as antifolates. Agents including 5-fluorouracil and methotrexate (and related antifolates) bind to folate-dependent enzymes by mimicking the structure of folate but do not serve the same biological function. These agents enter the cell and inhibit folate-dependent reactions associated with DNA synthesis and result in cell death. Antifolates are used in the treatment of many cancers, Crohn's disease, rheumatoid arthritis, lupus, and other autoimmune disorders.

### Folate Deficiency and Disease

The most common impairments of folate metabolism result from inadequate folate intake, certain drug therapies, smoking, malabsorption disorders, alcoholism, genetic mutations, and subtle individual genetic variations that occur normally in populations. Additionally, certain dietary factors can interfere with folate absorption in the gut and result in malabsorption of the vitamin. Inadequate folate

status has been reported in many population groups including pregnant and lactating women, women twenty to forty-four years of age, adolescents, and the elderly. Folate requirements are greatly increased during pregnancy due to the high demand for folate by the growing fetus and placenta. Folate deficiency can present itself clinically as megaloblastic anemia, a clinical condition associated with enlarged red blood cells due to decreased DNA synthesis. Other clinical symptoms include an inflamed, red-looking tongue, nausea, vomiting, diarrhea, anorexia, hyperpigmentation, and fever. Folate deficiency during pregnancy is highly associated with several congenital defects including spina bifida. Population studies implicate impaired folate metabolism in other pathologies including cardiovascular disease, colon cancer, cervical dysplasia, and pre-eclampsia.

### Folate and Homocysteine

One of the first biochemical indicators associated with impaired folate metabolism is increased serum homocysteine (resulting from decreased methionine synthesis). Both folate and vitamin B<sub>12</sub> are required for converting homocysteine to methionine. Plasma homocysteine level is a sensitive marker of folate status, but homocysteine can be influenced by other vitamins, including vitamin B<sub>6</sub> and B<sub>12</sub> status, as well as age. The relationship between folic acid and homocysteine levels in the body is important because of the association between homocysteine and vascular disease. Elevated plasma homocysteine is now considered an independent risk factor for atherosclerotic vascular disease. The risk of cardiovascular disease rises in proportion to an individual's serum homocysteine concentrations. Some studies also suggest an independent role of folate deficiency in cardiovascular disease. The relationship between homocysteine and disease is not understood, but two mechanisms are the focus of current research. Homocysteine contains a reactive thiol group that can modify proteins and affect their function. Alternatively, homocysteine can also be converted to S-adenosylhomocysteine, which is a potent inhibitor of many methylation reactions that modify DNA proteins and influences gene expression. Either or both of these mechanisms may account for pathologies that are associated with elevated homocysteine in humans.

### Dietary Recommendations

In 1998, the National Academy of Sciences released the Dietary Reference Intake (DRI) values for folate that include a recommended dietary allowance (RDA) of 400 micrograms for males and females aged fourteen years and younger. For these individuals, the source of folate is not important. However, it is recommended that women of childbearing age consume an additional 400 micrograms of folic acid per day from fortified foods and/or supplements in addition to the intake of food folate from a varied diet. It is critical that women be folate-sufficient prior to pregnancy, since most birth defects that result from folate deficiency occur before the twenty-

ninth day of pregnancy, often before the woman realizes she is pregnant. Maintaining adequate folate status is especially critical for women with a history of bearing children with neural tube defects, to prevent future incidence of birth defects. Pregnant women should consume an additional 600 micrograms of synthetic folate per day in addition to a naturally folate-rich diet. It is not normally recommended that anyone consume more than 1 milligram of folate per day.

The RDA is expressed as dietary folate equivalents (DFEs) because synthetic folic acid is more easily absorbed in the intestine than naturally occurring folate. One microgram of naturally occurring food folate is equivalent to 0.6 microgram of folic acid from fortified foods or supplements consumed with meals and to 0.5 microgram of supplements not consumed with meals. Because of recent federal regulations for food fortification, synthetic folic acid can now be found not only in dietary supplements, but also in enriched grain products (0.43 to 1.4 micrograms of folic acid per pound grain product) such as flour and pasta. Initial results from the fortification program indicate that plasma folate levels have more than doubled among adults who do not use folic acid supplements. The effect of this program on reducing spina bifida and other folate-associated birth defects and pathologies is yet to be determined.

**FOLKLORE, FOOD IN.** While doing folklore fieldwork with the Singing and Praying Bands of tide-water Maryland and Delaware, the present author observed a minor event that made a major impression on him. The Singing and Praying Bands are groups within some African-American Methodist churches in the Chesapeake Bay area of the East Coast of the United States that hold services in which they sing and pray with escalating fervor to invoke the Holy Spirit and to convert the unsaved. That day in particular, they were having no success: the Spirit simply was not stirring. Finally, one senior member slipped into the center of the singing group and called out the following verse to be added to the hymn:

Old man Moses must be dead;  
Children in the wilderness crying for bread.

This couplet combines two episodes from the book of Exodus. The first line refers to the episode when Moses ascended Mount Sinai and disappeared from the camp of the Israelites, causing them to wonder about his continued survival (Exodus 32:1). The second line refers to the Israelites' muttering against Moses for leading them out of Egypt, only to face starvation in the wilderness (Exodus 16:2–3). In response to the murmuring of the Israelites, God caused bread, or manna, to rain from the heaven. This couplet, drawn from a large repertoire of folk poetry distinct to the band, summarizes the attitude of desperation of the Israelites, and applies their condition to that of the band members on that particular summer Sunday afternoon.

The moment the singing group heard this verse, they increased the energy of their singing, their clapping, and their foot stomping in a way that finally was successful in invoking the Holy Spirit. After receiving this blessing from the Spirit, people in the bands seemed to decide that the service could begin to wind down.

### **GREAT GREEN GLOBS OF GREASY GRIMY GOPHER GUTS**

Great green globs of greasy grimy gopher guts  
Mutilated monkey meat  
Little chopped up birdies' feet  
Great green globs of greasy grimy gopher guts  
And I forgot my spoon.

So give me a sandwich with pus on top  
Monkey vomit and camel snot  
French fried eyeballs dipped in goo  
Have some (Mom or Dad) it's good for you.

This use of "bread" as a metaphor for the Holy Spirit among the bands is not uncommon. On other occasions, the same groups append the line "Bread of heaven, bread of heaven, feed me till I want no more"—a line drawn from the hymn "Guide Me, O Thou Great Jehovah" by William Williams (1717–1791)—to the end of long, lined out hymns. They sing this line repeatedly as a meditation to focus the minds of the members of the group so that they can all come together in religious solidarity, as the disciples did on the day of the Pentecost (Acts 2:1–2), and the Spirit may become manifest among them.

In the liturgical language of the Judeo-Christian tradition, the word "bread" is often used as a metonym for food in general. Used as a symbol of all bodily nourishment, it may also become a symbol of the Holy Spirit, which provides band members with what they refer to as their "spiritual food." This story and the interpretation of its larger implications can be usefully employed to introduce the rich subject of food—in this case, bread—in folklore.

In actuality, references to food are made in all genres of folklore, and presumably in all cultures around the world. References occur in folktales (such as the story Hansel and Gretel, in which the witch's house is made of gingerbread and sugar candy, and Hansel almost becomes dinner himself), in folksongs (the hobo anthem, "The Big Rock Candy Mountain"), in folk dance (the Cake Walk, the Mashed Potato), in festival pranks (trick or treat during Halloween), in costume (a couple dressed as "a night at the movies" for Halloween, one attired as a theater ticket, the other as a bag of popcorn), and even in vernacular architecture (American roadside vernacular architecture includes buildings such as a duck-shaped drive-in restaurant selling roast duck as well as fast-food stands topped with sculptures of hot dogs amply slathered with condiments, as documented in the influential book on postmodern architecture *Learning from Las Vegas*).

While it would be impossible to develop a unifying theory or classification scheme that accounts for all such references to food in folklore, a loose framework of analysis can provide a prism through which the subject of food in folklore can be viewed. In order to establish such a framework about food in folklore, however, we should first examine the subject of folk cuisine itself, and folk eating habits. Together, these constitute the domain that scholars in the field of folklore and folklife have come to call "foodways." The food traditions of any one community include not just recipes, but the methods by which foods are gathered, stored, prepared, displayed, served, and disposed of. Such traditions include also culturally transmitted rules that govern ideas of health and cleanliness as related to food. Further, the academic analysis of foodways includes the study of foods that are especially esteemed or shunned by any particular identity group, and the study of culturally specific rules governing the contexts in which particular foods may or may not be eaten.

Like the North American cowboy, the Argentine gaucho plays a large role in South American folklore. Here a trio of gauchos is depicted preparing *churrasco* on the pampas. Detail from a 1951 menu for La Cabaña Restaurant y Grill in Buenos Aires. ROUGHWOOD COLLECTION.

In events that involve the serving of food—from ordinary meals to holiday feasts—ties of reciprocity between networks of preparers, as well as relationships between those preparing and those being served, become articulated. Differing customs pertaining to food also signal boundaries between differing groups of identification. Food events, therefore, tend to provide a rich subject for folk commentary about any one group's culture and social organization.

It is axiomatic in the field of folklore that folklore genres—whether food, story, art, or song—are expressive culture. Such expressive culture is not passively received and mechanically reproduced. Instead, when engaged in folk expression, individual tradition bearers in any cultural setting consciously build on the past to create the emerging culture. A corollary to this axiom is the idea that any such folk expression is rhetorical in intent: That is, it is designed to persuade its audience of the validity of its point of view about a subject. From this axiom and corollary, it follows that folklore about food in particular—that is, food in folklore, the subject of this essay—can be viewed first as expressive culture that offers a commentary on the foodways of the people from whom

the commentary arises, and second as commentary designed to persuade its hearer or viewer of its point of view.

Folkloric commentary about food can be glowingly positive, even sentimental, or intensely negative. These extremes manifest themselves positively in festive, holiday cooking on the one hand, and negatively in food taboos on the other. Americans still listen longingly to songs or poems about chestnuts, wassail, and sugar plums long after these foods have disappeared as a regular feature of their diet. Americans do not just bake gingerbread men and cookies shaped like stars during this time of year. These foods are also turned into folk art when they are used as decorations on Christmas trees, thereby offering a commentary about our reverence for them as holiday foods.

Nontraditional food choices, conversely, may elicit disgust. In the United States, children's folklore, for example, abounds with songs or sayings about foods thought to be inedible. Children may enjoy the playing with the images of such foods to elicit disgust in others. In doing so, they demonstrate that they have internalized many of their culture's food taboos. In general, it is dif-

## GOOD, THOUGH!

Chorus: Oh, the Wild River crew is a rough old crew,

And I'll tell you the reason why:  
We live on brew and cat-liver stew,  
And a daily piece of moose-turd pie.

1. Old Jigger Jones kicked the knots off logs  
With his bar feet, so they say,  
But he hung around Wild River too long,  
And it drove him nuts one day.

2. Now old Jigger Jones he got pretty tired  
Of doin' all of our cookin',  
So he says, "If I hear one more guy bitch,  
For a new cook you'll be lookin'."

3. Jones was out in the woods next day  
Chasin' a big deer herd;  
Coming back to camp without any luck,  
He slipped upon some fresh moose turds.

4. He scooped 'em up in his old game bag,  
The grin on his face was sly;  
He thought the boys would surely bitch  
If they tried a piece of his moose-turd pie.

5. The boys come in for supper that night—  
Their appetites were high;  
They chawed their way through a ten-course meal,  
Then they started in on the moose-turd pie.

6. One by one the boys turned green,  
Their eyeballs rolled to and fro;  
Then one guy hollered as he sank to the floor,  
"My God, that's a moose-turd pie!  
[Shouted] Good, though!" [cheerfully, with eye-  
brows and one finger raised]

In Barre Toelken, *Dynamics of Folklore*, Boston: Houghton Mifflin, 1979, pp. 179–180.

difficult to say a great deal about an item of folk expression without knowing the author, the author's motivation, the context, or the audience response. But in a society in which many children spend their formative years eating often nondescript cafeteria foods, they may also be offering a commentary on institutional food when they sing a song such as "Great green globs of greasy grimy gopher guts, mutilated monkey meat, little chopped up birdies' feet. . . ." Similarly, young people who refer to certain cafeteria offerings as "mystery meat" can be thought of as authoring a rather negative commentary on the food they are being served.

Other folk commentary about mass-produced foods is not so humorous. One urban legend tells of a couple who buy a fast-food dinner of fried chicken. When the

woman bites into her meal, she finds that she has been served breaded, fried rat. The story can be viewed as a commentary on the anxiety of many Americans about potential contamination of industrially processed food. The folklorist Gary Alan Fine, who examined a large number of variations of this legend, suggests that the story also seems to chastise contemporary American women. Since the victim is always the woman of the couple, the legend seems to be contending that the whole episode might be her fault: if she had remained in the home and provided her partner with home cooking, the event would never have happened.

In African-American folklore, similar worries about the adulteration of the food supply have on occasion become transformed into rumors that blacks are vulnerable to being specifically targeted with toxic substances. In the late 1980s, folklorist Patricia Turner documented a rumor circulating among some African Americans to the effect that Church's Fried Chicken was owned by the Ku Klux Klan, and that their food contained a substance that would sterilize black men. The rumor seems to have been exacerbated by the fact that Church's located its franchises primarily in inner-city neighborhoods and did little advertising as compared with other fast-food companies. Furthermore, by offering food commonly identified with the African-American home kitchen, Church's had transgressed into somewhat sacred territory. Those who reported hearing the rumor had no problem believing that the Klan was capable of carrying out such a widespread secret plan, as the rumor claimed.

Another cycle of recent urban legends focusing on the disgust elicited by the eating of tabooed foods developed when Southeast Asian refugees began immigrating to the United States after the war in Vietnam. When several thousand refugees settled in Stockton, California, a rumor arose in adjacent communities that an expensive pet dog had disappeared; a neighbor's boy claims he saw a Vietnamese family eating the dog, and remains of the dog were later discovered by a garbage collector. While appearing to focus on racial stereotypes about the divergent eating habits of the new immigrants, according to researcher Florence Baer, this legend actually comments quite articulately on the white community's fear that new immigrants were swarming into the country and consuming so many resources and social services that none would be left for longer-term citizens.

Yet folk commentary on food taboos is not exhausted by urban legends about contamination of the food supply or diversity of eating habits. The most severely tabooed substances, according to esteemed folklore scholar Roger Abrahams, are human flesh, feces, and carrion. Nevertheless, items of folklore that speak of violating these taboos abound. In several predominantly male societies, for example, such as the logging camps of Maine, and railway construction camps in the West, a story known to folklorists as "Moose Turd Pie" has circulated as a song, a legend, and a joke. As the story is told

by folksinger Utah Phillips, a new worker comes to work without knowing the workplace custom that whoever complains about the food will have to do the cooking until the next person complains. When the new man inevitably complains, he is forced to cook. To rid himself of the job, he sets about making a pie out of moose feces. On taking a bite of the pie, one of the more experienced coworkers calls out his disgust, "Moose turd! . . . Good though!"

This story comments on foodways in several ways. First, it humorously remarks on the horror of eating a grossly tabooed substance. Second, it seems to comment on gender roles in food preparation by taking for granted the idea that the men involved would rather do physically demanding manual labor than cook, which is often perceived as women's work. Third, the version told in concert by Phillips hints at traditional hazing practices to which new workers in male societies are sometimes subjected. During such hazing practices, the rookie worker is inducted into full-fledged membership in a group only after being ritually feminized—in this case by being assigned a "woman's" job. It also hints that the appropriate way for the new worker to endure such an initiation with his sense of masculinity intact is to develop a prank in retaliation that is as humiliating to the hazers as the hazing to the low man on the totem pole.

Folklore about food can reveal a great deal about gender identity. That life on the western frontier of the United States necessarily required pioneers to enlarge their repertoire of foods is incontrovertible, as folklorist Charles Camp has discussed in his review of the foodways data gathered by the Federal Writers Project during the New Deal years. Ranchers and cowboys who, like Native Americans, believed that no part of the animal on which their livelihood depended should be wasted on slaughter, developed the habit of eating bull testicles, which they often have referred to as "rocky mountain oysters." In Montana, where this specialized food may also be referred to as "Montana tendergroin" or "cowboy caviar," several festivals have come to be held every year in which all festival goers combined eat several tons of rocky mountain oysters. While there are a number of such events around the state, the first and largest, called "the Testicle Festival," takes place in Clinton, Montana, just east of Missoula.

Proverbial expressions in American English seem to imply that American males admire the virility of bulls. One speaks of being "strong as a bull." Manual labor that requires heavy lifting is called "bull work." A robust stock market is a "bull market." The eating of bull testicles can be interpreted as the human male's appropriating the bull's virility for himself. A festival that features this as its *raison d'être*, becomes in turn a celebration of human masculinity.

But the eating of such identifiable body parts of the bull also demands of many people who attend a suspension of some of their usual food inhibitions. Eating of

such animal organs as eyeballs, brains, or sexual organs would under normal circumstances elicit displeasure from many Americans, old cowboy traditions notwithstanding. At the Testicle Festival in Clinton, Montana, this relaxation of eating habits—combined with the celebratory drinking of intoxicating beverages—seems to cause a lowering of other inhibitions as well. Human body parts that are usually covered are publicly displayed. Behaviors usually undertaken in private may be acted out or simulated in public. The result is a carnival-like folk festival the rationale of which celebrates masculinity in a way that inverts usual cultural inhibitions and exposes—as good festivals do, as good folklore does, and as some folklore about food does—human passions in their most naked form.

**FOOD, COMPOSITION OF.** Food composition activities include data generation in an analytical laboratory, data compilation in a database management system, data dissemination through print and electronic media, and data use by various professional and lay users.

Historically, food composition activities were limited to data on nutrients. Increasingly, food composition work deals with data for any component found in food: nutrients, bioactive nonnutrients, antinutrients, pesticide residues, other contaminants, additives, and more. A single food composition database, with proper documentation, can accommodate data on all these types of components.

### Sectoral Elements

Food composition data are useful to many professions and sectors. Health, agriculture, environment, and trade are the sectors most fundamentally involved in food composition activities. Over time, agriculture has been the dominant sector involved in food composition research and service. This is demonstrated most clearly in international organizations such as the Food and Agriculture Organization of the United Nations (FAO), with a history of food composition work dating back to its inception in the 1940s; and in countries having the longest history of formal food composition activities such as the United Kingdom, where the Ministry of Agriculture, Fisheries and Food has had most of the responsibility, and the United States, where responsibility lies with the United States Department of Agriculture (USDA), and has since the late 1800s. Nevertheless, more than half of the participants in food composition conferences, and the researchers publishing food composition papers and books, are health sector professionals. In many countries it is the health sector that provides a high percentage of the funding for the work, and constitutes the highest percentage of the users of the information. Involvement of the environment sector is becoming increasingly important as it relates to the composition of indigenous or protected plant and animal species used as foods, and the content of environmental chemicals in the food supply. Trade has also gained more dominance in recent years.

Nutrient information panels on processed foods have become regulatory requirements in many countries. And analytical data on both nutrient and contaminant content are necessary documentation for global food trade.

### Organizational Elements

**The international level.** INFOODS, the International Network of Food Data Systems, was established in 1983 by United Nations University (UNU), with an organizational framework and international management structure that includes a global secretariat and regional data centers. Its mandate is "to improve data on the nutrient composition of foods from all parts of the world, with the goal of ensuring that eventually adequate and reliable data can be obtained and interpreted properly worldwide." In the mid-1990s, the Food and Agriculture Organization joined UNU in partnership for INFOODS. The main activities of INFOODS at the international level include development of technical food composition standards, assistance to Regional Data Centers and individual countries in developing their food composition activities, and publication of the *Journal of Food Composition and Analysis*.

**The regional level.** There are seventeen Regional Data Centers in operation. Some were created in the mid to late 1980s and have well-established and effective coordination (for example, LATINFOODS, ASEAN-FOODS, OCEANIAFOODS, and EUROFOODS); some are relatively new, yet making progress; and a few have been newly created and are trying to establish their regional or national priorities and capabilities. Regional food composition tables have been prepared, both electronically and in printed form (for example, Pacific Islands, ASEANFOODS, LATINFOODS), and many regions have regular food composition coordination activities and technical task forces involving all the individual countries in the region.

**The national level.** Most countries have food composition activities of one form or another. A national food composition program is usually the result of the combination and coordination of activities, within some defined administrative framework, related to food composition data generation, compilation, dissemination, and use. A steering committee is a useful structure, functioning well in many countries. This steering, or advisory, committee is ideally composed of individuals directly involved in food composition work, that is, the data generators, data compilers, and data disseminators. Crucial to the effectiveness of a steering committee is the involvement of data users. The users can be selected among dietitians, nutritionists, food industry personnel, and consumer group representatives.

Often a single organization holds the overall responsibility for managing a national food composition program, yet it is rare that a single organization accomplishes all the activities itself. Regardless of their affilia-

tions, the laboratory-based data generators must interact closely with the data compilers, and the compilers must interact closely with the data users. In most countries there are other agencies with activities that have direct or indirect relationships with food composition data, but operate in concert with the national program. In addition to the desirability of a coordinated national approach for accomplishing essential activities, it is productive and important for a national food composition program to operate in conjunction with its Regional Data Center, and with ongoing international activities.

### Technical Elements

Data generation is the process whereby foods are sampled, prepared for analysis, and analyzed in the laboratory. Data compilation is the process whereby the data from the laboratory are examined, manipulated, and incorporated into a food composition database. Data dissemination refers to the preparation and publication of books and electronic data products, which are made available to users in the various sectors. Data use also includes the application of these data to tasks, projects, and programs in the various professional sectors.

**Data generation.** Sampling, the process and procedures for obtaining foods that are representative of those available and consumed, is fundamental to any food composition activity. Preparation of a sampling plan often requires involvement of all the major contributors to a food composition program. Data generators must be involved in the sample collection, or at least the scheduling of sample collections, so that samples may be immediately and properly prepared for analysis. Data compilers must be involved because information on the sampling plan and details such as when and where sampling took place are important parts of a food composition database's metadata. Data users must be involved because they have the best appreciation of the foods that need to be analyzed, and often the location from which the samples should be collected. The services of a statistician are useful for developing a sampling plan, because representativeness is dictated by the number of food units collected—and analyzed—to achieve the goal. The goal might be to compare compositional differences between cultivars, or to achieve year-round, nationwide mean values for a food composition database. The overall quality of food composition data is determined largely by the sampling plan.

The collected samples must be properly handled so that they arrive at the laboratory without changes that might affect their composition. The key component, crucial to the correct determination of almost all other food components and most easily affected by improper handling and storage, is water (moisture). Once samples are delivered and documented, they are prepared for analysis. Preparation may involve separation of edible from inedible portion (for example, removal of bones from fish, or skins and seeds from pumpkins); kitchen-type prepa-

ration (for example, boiling rice); or combining of many samples into fewer samples (for example, combining five brands of similar biscuits into one representative composite sample). After this type of preparation, samples will be stored, or immediately analyzed. As with sample collection and sample handling, proper documentation of all aspects of sample preparation is essential.

**Analyses.** Most laboratories undertake a limited range of analyses for food composition purposes. This includes a set of core components and then additional components of interest, for example, laboratory research dealing with diet-related health problems. Core nutrients usually include the complete range of proximate components (water, nitrogen for the protein calculation, fat, glycemic carbohydrate, dietary fiber, ash, alcohol where relevant, and an energy value using factors applied to the energy-yielding proximates), some vitamins, and some nutrient elements. Additional components of interest often include cholesterol, individual fatty acids and aggregations of fatty acids (for example, total saturated fatty acids), carotenoids (both provitamin A carotenoids and antioxidant carotenoids with no provitamin A activity), other bioactive nonnutrients, heavy metals, and some so-called antinutrients (for example, phytates). Proper laboratory practices must be strictly adhered to, as well as laboratory quality assurance and quality control procedures, and details of analytical methodologies must be properly documented.

**Data compilation.** Data compilation requires a relational database management system, and adherence to international food composition standards where they exist. The database should accommodate numeric data, text, and graphics. Ideally, all the raw analytical data, and their attendant documentation, should be captured. The system should then be able to manipulate these data in many different ways. The same data system should provide an exhaustive reference database and any number of abridged user databases to satisfy the broad range of user requirements for food composition data. Many compilers only capture mean values, a practice that will satisfy many users. Other compilers provide more information, and therefore higher-quality databases, by including the number of samples and some expression of their variability. Other compilers are able to capture all the analytical data and prepare user databases with ranges (that is, high and low values), medians, and many different statistical expressions of the data, satisfying a broader spectrum of users and ensuring the highest quality database.

Some compilers prepare their databases with aggregations, excluding the baseline data (for example, a calculated value for vitamin A in retinol equivalents [RE] without individual values for retinol and each provitamin A carotenoid), whereas other compilers provide the analytical data for the individual components, in addition to the aggregations. This latter practice should be encouraged, since conventions for calculating aggregates based

on biological activity change, and many of these individual components have other functions in addition to their roles as provitamins.

In data compilation, all food composition data can be included in the database. Complete information for all components in all foods is not necessary. Ideally, a database with one thousand foods should have complete information for core nutrients, but should also be able to accommodate sporadic data for other components in the foods included.

The early work of INFOODS included the development of standards and guidelines for compiling food composition databases for national and regional use (Rand et al., 1991), standards for unambiguously identifying food components (Klensin et al., 1989), and standards for ensuring international comparability and interchange of food composition data (Klensin, 1992). These standards are being maintained and further developed by INFOODS expert committees and consultative groups.

**Data dissemination.** With appropriate data compilation, food composition data can be disseminated in many different forms to satisfy all user requirements. Table 1 shows examples of some of the common forms in which food composition data are disseminated. Data disseminated as a set of relational files offers users with very specific needs, or those with customized software, the opportunity to use the data as they wish. Other common dissemination formats provide the types of information most often required by users.

Different countries have different approaches for charging, or not charging, for their data and data prod-

ucts. The United States Department of Agriculture prepares the largest single body of food composition data in the world and disseminates it freely via the World Wide Web, as both a downloadable set of relation files and a searchable reference volume.

**Data Use**

Food composition data are the basic, most fundamental information resource for most nutrition activities. Some of the specific uses of food composition data, along with examples of their uses, are listed below by sector.

**Health sector.** Food composition data are used in health protection activities in most countries in the world. “Food control” laboratories monitor mostly harmful components of foods. Other health protection activities include food composition activities involving total diet surveys or “market basket surveys” designed to determine the risk to populations from intakes of selected nutrients, antinutrients, and contaminants. The sampling, sample preparation, sample handling, analyses, and reporting requirements are virtually identical to the requirements of other food composition activities.

**Health promotion.** Health promotion activities include campaigns aimed at reducing or increasing the intake of certain nutrients in certain populations. Examples include healthy heart campaigns, typically using energy, fat, fatty acid, and cholesterol compositional data to educate the public about diet-related cardiac morbidity and mortality. In many developing countries, health promotion focuses on micronutrient data, including the necessity for including iodine in salt and provitamin A carotenoids in fruits and vegetables.

TABLE 1

Data dissemination forms					
Output form	Foods	Components	Basis	Numeric data	Metadata
Set of relational files	All	All	Per 100 g e.p.; amino acids in mg/gN, fatty acids in g/100 gTFA; others as available	Mean, standard deviation, standard error, number of samples; raw analytical data as requested	Various; often as requested per sample, or per nutrient per record
Diet analysis software product	All	Subset of core nutrients with no missing values	Per 100 g or any serving size as user selection	Mean	Not provided
Tables, large reference volume, or Web format	All; portrait format; one food over 1–2 pages	All	Per 100 g e.p.; amino acids in mg/gN, fatty acids in g/100 gTFA	Mean, standard deviation, standard error, number of samples	Abridged and general; provided in introductory pages
Tables, concise	Subset of 200–800; landscape format; 15–25 foods over 1–2 pages	Subset of 12–28	Per 100 g and up to two common serves	Mean	Very general

e.p.=edible portion; N=nitrogen; TFA=total fatty acids.

*Clinical research.* Food composition data are central to many clinical research trials. Examples include studies focusing on amino acid digestibility in ileostomy patients, vitamin A intake in breast-fed infants, and serum cholesterol levels in vegetarians. Knowledge of the composition of the test and control food(s) and/or diet(s) is fundamental to these studies.

*Clinical care.* Clinical dietitians must know the composition of foods in order to provide effective and therapeutic meals in a clinical setting. Special diets for patients are often based on individual nutrients in the foods: low-sodium diets for hypertensive patients, diets low in saturated fats for heart disease patients, diets containing proper ratios of protein and fat, and those containing the proper amount of carbohydrate for diabetics, high-protein diets for burn patients, diets containing low phenylalanine for phenylketonuric patients, and so forth.

*Epidemiological research and diet studies.* Epidemiological and diet studies take many forms. Some studies address food intakes and relate them to nutrient content of the diet and the incidence of diseases. Interpretations of the findings of these studies often focus on individual nutrients. Recent examples include Dutch and Finnish studies of dietary antioxidants and lung cancer, and studies of vitamin E and colon cancer among Iowa women.

*Public health policies.* Many public health policies relating to noncommunicable disease focus on food composition. Such policies set forth nutrition goals and guidelines and include recommended dietary intakes (RDIs). An example of such goals and guidelines is “choose a diet low in fat, saturated fat, and cholesterol”; and an example of an RDI is “females between the ages of fourteen and eighteen should get 15 mg of iron daily.” In order for such recommendations to be useful, both health professionals and the public must have access to data on the nutrient composition of foods.

*Nutrition intervention policies.* Nutrition supplementation typically takes the form of fortification of the food supply or supplementation of the population. Examples of food fortification include the addition of iodine to salt (most countries), of vitamin A to sugar (for example, in Guatemala), and of minerals and B vitamins to refined cereal products (United States, United Kingdom). Such interventions are only carried out after the nutrients in the food and water supply of a country have been studied, and a baseline position has been established and carefully monitored over a period of time.

*Household food security.* Although food security is an issue that spans the health, agriculture, environment, and trade sectors, household food security is usually considered to be a health sector issue. Knowledge of the nutrient content of the foods consumed by household members is a precondition for assessing household food security.

*Agriculture sector.* The intensive livestock industries require accurate nutrient composition data on the feeds used. These data are generally far more extensive than

those required for human foods, and include many micronutrients and individual amino acids. “Performance” in these animals usually refers to weight at time of slaughter; muscle tissue to fat tissue ratios; and in the case of milk-producing animals, an accurate profile of the proximate composition (protein, fat, lactose, water, and ash).

*Food security.* National and global food security is generally considered an agriculture sector issue related to food production, rural development, irrigation, fertilizer and pesticide use, crop yields, and so on. A common tool used to assess national and global food security is the FAO food balance sheets that examine, at the commodity level, the amount of food available to a country. The amount of food is then converted into individual components and reported as the amount of protein, fat, and energy available per person per day from the domestic food supply. Food composition data assigned to the commodity data are the basis for many food security assessments, including FAO’s yearly report on the number of undernourished people in the world.

*Export food industries.* The agriculture sector is responsible for ensuring that food exports meet the regulatory requirements of the intended market. Food composition data are important, as product specifications (for example, the fat content of butter) and as nutrition label panels.

*Domestic food production.* Agriculturalists have long professed that malnutrition is not just a health problem, but also an agriculture problem. Increased consumption of imported food commodities has brought about changes in food patterns and diets that have contributed to the increase in diet-related health problems previously unheard of in certain parts of the world. Agricultural extension workers are combating the incidences of diet-related diseases in some developing Pacific Island countries by using nutrient composition data in family food production, helping families in designing home garden projects to supply nutrients that would otherwise be consumed in insufficient quantities.

*Molecular and traditional food plant and animal breeding.* Breeding has been done to modify certain nutrients in foods. Familiar examples include corn bred for higher lysine and cattle bred for lower fat content of the carcass.

*Environment sector.* Knowledge of the nutrient composition of the native diet of endangered animal species is an important requirement for protecting them. In New Zealand, scientists have undertaken studies to determine the nutrient composition of the original diets of birds in their native habitat, to ensure that the same nutrients in the same quantities and proportions were being supplied in their human-made offshore island sanctuaries and other protected, artificial habitats.

Climate change also affects food composition. Ozone depletion affects both food production and the composition of crops and agricultural products. Like ozone depletion, global warming affects agriculture in terms of

production implications. Its other major effect, now and in the future, is the creation of conditions that will permit certain food products to be cultivated where temperature conditions did not permit their cultivation previously. This will alter the food supply, and along with it the nutrient composition of certain foods, in certain countries. Food composition data have been used as markers in modeling and predicting environmental change, for example, monitoring the changes in fatty acid composition of fish to chart the climatic phenomenon of El Niño.

**Trade sector.** Trade has emerged in recent years as one of the more important and demanding of the sectors involved in food composition activities. Food composition in various forms features in the World Trade Organization agreements, the Codex Alimentarius Commission and several of its committees, multilateral and bilateral trade agreements, and national food regulations and standards. More than other sectors, trade has illustrated most poignantly the need for standards and harmonization in technical food composition activities. Many trade-related court cases have involved food composition data, both in the charges filed and in evidence presented, and many of the food product detentions and rejections at U.S. borders are due to the absence of the Nutrition Facts panel of nutrient content data.

**FOOD, FUTURE OF: A HISTORY.** Food is the first of the essentials of life, the world's largest industry, and our most frequently indulged pleasure. Food means creativity and diversity. Food is also the object of considerable concern and dread. Probably nothing is more frightening than the prospect of running out of food. Reflecting humanity's deep-rooted heritage of food insecurity, there have always been prophets warning us against complacency. And given mounting environmental concerns about population growth, global warming, soil erosion, water scarcity, agrochemical pollution, energy shortages, diminishing returns from fertilizers, and so on, it seems justified to wonder whether the banquet is over. Will our grandchildren's grandchildren enjoy the dietary abundance that most of us take for granted? And how will we feed a rapidly growing, urbanized population in the developing world?

As policy analysts debate scenarios, starkly different forecasts and proposals emerge. Some futurists predict unprecedented affluence, while others worry about global shortages and famine. Some are confident that the conventional industrial agriculture can take care of the future, while others see the status quo as a sure route to disaster. While many in government, academia, and industry look to new technologies—especially genetic engineering—to feed the world tomorrow without any modification of modern high-consumption values, others propose "low-tech" alternatives organized around smaller-scale, localized food systems dependent on a return to a more traditional appreciation of limits.

#### The Policy Debate

The European-American policy debate dates back at least as far as the late eighteenth century. When the economist and clergyman Thomas Malthus (1766–1834) published his *Essay on the Principle of Population* (1798) in response to "the speculations" of the French mathematician and philosopher the Marquis de Condorcet (1743–1794) and the English radical philosopher William Godwin (1756–1836), he crystallized a three-way argument about the future of the food system. As the demographer Joel Cohen writes in *How Many People Can*

*the Earth Support?* (1995)—an analysis of the carrying-capacity debate—there are three enduring positions on the question of how we might feed everyone adequately in the future: 1) bake a bigger pie; 2) put fewer forks on the table; or 3) teach everyone better table manners. Condorcet offered the “bigger pie,” or techno-cornucopian position: since there are no limits on human ingenuity, science and industry can always devise ways to bake bigger and better pies for everyone. Doubting the cornucopians’ faith in technology, Malthus took the “fewer forks” position: humanity’s capacity for reproduction outruns the farmers’ capacity for production, or the scientists’ capacity for miracles, so prudence dictates a more conservative, less expansive approach to the future. Profoundly pessimistic about human nature, Malthus also voiced severe doubts about Godwin’s romantic-utopian “better manners” position, which held that in an egalitarian society with altruistic values, people would figure out ways to share nature’s bounty and overcome scarcity. Godwin’s democratic optimism was inherited and elaborated by both socialists and liberals who promoted a more equitable redistribution of resources as the solution to hunger.

In the two centuries following Malthus’s *Essay*, the debates went through several cycles, becoming more pressing in particular periods such as the 1890s, the 1920s, the late 1940s, the 1970s, and the 1990s. These scares were precipitated by certain conditions and events, such as food price inflation, spikes in birthrates, exceptional environmental stresses, and acute cultural anxieties about migration and rapid demographic change. The discussion also had a self-reinforcing synergy as the three debating partners fed off each other: Doubting that science could keep performing miracles, Malthusians predicted still more hunger. Defying Malthus, cornucopians took steps to produce more food. Pointing to mounting surpluses, egalitarians critiqued an economic and political system that fattened the rich with cheap meat while depriving the poor of basic grains and depleting the soil. The debate continues today. Citing two hundred years of unexpected, indeed miraculous, productivity gains, cornucopians at the World Bank, the U.S. Department of Agriculture, and the leading agribusiness corporations hope for still more yield improvements through biotechnology. Citing two hundred years of environmental disaster and resource depletion, neo-Malthusians like Paul Ehrlich and Lester Brown worry about the limits to growth. And as over a billion people remain hungry amid mounting agricultural surpluses, neo-socialists like Frances Moore Lappé and Vandana Shiva argue that only with a more equitable economic system can the poor feed themselves.

### Popular Visions of the Future

It is important to note that discussion of these issues has not been confined to the professionalized realm of academic demography, agricultural economics, and agronomy.

Rather, it can be found in a diverse array of expressive, prescriptive, and material forms. Thus, speculative fiction has been a primary forum for the expression of serious doubt about the ability of modern technology to keep up with population growth. Indeed, Godwin’s daughter, Mary Shelley, wrote one of the first cautionary tales about technological hubris in *Frankenstein* (1818), while her husband, the poet Percy Bysshe Shelley, promoted vegetarianism as a more just and sustainable food system in *Vindication of Natural Diet* (1813). Having been conditioned by popular novels like Aldous Huxley’s *Brave New World* (1932) and films like *Soylent Green* (1973) to equate cornucopian ingenuity with distasteful synthetic foods, many modern consumers remain understandably skeptical about the latest claims of genetic engineers. Similarly, utopian novels have long offered a lively medium for the presentation of egalitarian alternatives. Thus, during the Progressive Era of the late nineteenth and early twentieth centuries, many utopian writers followed Edward Bellamy (*Looking Backward*, 1888), Mary E. Bradley Lane (*Mizora: A World of Women*, 1890), and Charlotte Perkins (*What Diantha Did*, 1910) in proposing scenarios that harnessed highly industrialized means of food production to socialistic distribution goals. In the 1970s, countercultural utopians Ernest Callenbach (*Ecotopia*, 1975) and Marge Piercy (*Woman on the Edge of Time*, 1976) inspired a generation of food radicals with their scenarios coupling localized, ecologically sensitive agriculture with communal, neotribal distribution and postmodern consumption—the outlines of what Kloppenborg, Hendrickson, and Stevenson have called sustainable “foodsheds.”

### Three Cornucopian Positions

Given the hegemony of techno-optimism in modern culture, however, the cornucopian position has probably had the widest dissemination, with promises of abundance available in many arenas and formats: supermarkets, restaurants, World’s Fairs, Disney theme parks (especially Tomorrowland and Epcot), food advertising, mainstream editorial opinion, and the space program. Popular cornucopian thought tends to divide into three very different views of the future: classical, modernist, and postmodernist. The classical future is a smooth continuation and elaboration of past progress, a future of ever bigger and better things made available largely through the materialistic, quantitative expansion of frontiers—overseas and under the seas, in deserts and in tropical forests, under the ground and in outer space. The classical view of the future is the most traditional and often employs the most imperialistic methods of expanding the food supply (and wealth), appropriating other lands, peoples, and resources.

The modernist future represents a distinct break with the past, a radically new vision based on the very latest technologies and scientific breakthroughs, often producing a simpler, more “streamlined” and consolidated result. If the classical future eyes the visible riches of untapped frontiers, the modernist looks for wealth in the invisible—nitrogen

from air, protein from microbes, energy from atoms, better yields through better genes. Suspicious of nature and tradition, the modernist vision is comfortable with the synthetic, artificial, and chemically fortified. Ultramodernistic solutions to the food-population dilemma include meal pills (a Victorian fantasy), meat analogues synthesized from soy, cellulose, and algae, and the space program's menu of tubed and "rehydratable" analogues.

While culinary modernism has been favored most by pure scientists, it may also tend to scare off consumers wary of extreme discontinuities. The postmodernist future is thus perhaps the most palatable and marketable because it blends the classical and the modern, envisioning, for example, a world of neo-traditional foods mass-produced by modernist means such as microwavable stir-fries, aseptically packaged chai, and "fifties-style hamburgers" cooked on automated grills. Recognizing the human need for "authentic" tastes, NASA's dieticians have abandoned tubed food in planning interplanetary meals that now include fajitas, pad Thai noodles, barbecued tofu, and curried lentils. Less confident in the new than modernism, more eclectic and multicultural than classicism, the postmodernist menu may reflect how most people actually approach and experience the future: one foot forward with the other planted in an imagined past.

**FOOD ARCHAEOLOGY.** As part of their general research, archaeologists have long been interested in food remains under the rubric of diet and subsistence. This work contributes to understanding the long-term historical development of food, and its impact on cultures. Recently, there has been increased interest in food ar-

chaeology (although it is not yet identified as a separate discipline), fueled by new technologies and curiosity about implications that go well beyond diet to the role food played in social organization, and ultimately, in the development of civilization itself.

As in all archaeology, there are essentially two broad periods that are of interest to researchers. The first is prehistory, before written records were kept. For that time, scholars are wholly dependent on the interpretation of archaeological finds. The second period is historical archaeology, during which literary and written sources, including poetry, frescoes, and government record-keeping, have been retrieved. Comparisons of excavated food remains with records is particularly valuable because the finds may either contradict or augment the historical record. For example, at the site of a former Roman villa on the Greek island of Lesbos, 7,300 animal bones from a wide variety of species, including goat, deer, hare, pheasant, capon, boar, suckling pig, sheep, lamb, starling, and woodcock, confirm contemporary reports of lavish banquets.

#### The Evidence

Direct evidence of diet consists of preserved food remains, both plant (paleoethnobotany) and animal (zooarchaeology); analysis of human bone and teeth; undigested stomach contents; and coprolites (fossilized feces). Collection and analysis of plant remains is often futile because most decay. If, however, they have been charred (burned), perhaps during a cooking accident, the material is preserved indefinitely. To collect and isolate tiny floral fragments, samples of excavated sediment may be placed in a flotation tank through which water is forced electronically, forcing the buoyant seeds, pollen, and grains to the surface. Once salvaged, these items can be dated by the system known as radiocarbon dating, based on carbon's known rate of very slow decay. Tiny grains of manioc, yams, and arrowroot from an ancient settlement in Panama, Central America, have been carbon-dated to five thousand to seven thousand years ago, providing the earliest evidence of cultivation of root crops in the Americas.

Microscopic examination of charred plant remains can also determine whether they were cultivated or wild, indicating whether the society was agrarian or hunter-gathering. Charring leaves silica ghosts of the epidermal cells that when examined under the electron scanning microscope reveal telltale markers that distinguish between domesticated and wild crops. Such investigation of grains, husks, and plant remains in China helped push back the date for earliest domestication of rice from 8,000 to 11,500 years ago, and pinpointed the location to the middle Yangtze River.

The more recent technique of DNA "fingerprinting" offers an alternative for establishing domestication. When applied to einkorn wheat, one of eight "founder crops" that launched agriculture in the fertile crescent of

the Middle East around 9000 B.C.E., the method pinpointed earliest domestication to the Karacadağ mountains of southeast Turkey.

### Skeletal Remains

Human bones provide a wealth of clues about diet. Isotopic analysis of collagen can distinguish chemical signatures of foods. It becomes possible to determine proportions of land to marine foods in the diet, for example, and even to demonstrate the relationship of nutrition to social class. Excavation of skeletons at the former Mayan city-state Caracol in Mexico established that the upper classes, living in the city center, consumed the best diets. The worst were documented in the surrounding inner-city slums while diet improved in the outlying “suburbs,” proof that socioeconomic class and nutrition were related even this early.

### Learning from Context

Diet may also be inferred indirectly by examining the context of food remains, the environment in which they were found: pottery with grain impressions; eating, drinking, and storage utensils with food residues; hearths where charred grain is found; and gravesites where cut or charred bone indicates funeral feasting. Chemical analysis of food residues from eating and drinking vessels, a technological advance, has provided detailed information about the ingredients used to make a dish. University of Pennsylvania archaeologists pioneered the use of infrared spectroscopy, gas liquid chromatography, and gas chromatography mass spectrometry to examine remains on cups and plates from the 2,700-year-old tomb of the legendary King Midas located in Turkey. Analysis of the protein and lipids allowed scientists to conclude that the menu for this royal funerary feast included barbecued goat or lamb; lentils in olive oil; honey and wine spiced with fennel and anise; and an alcoholic drink composed of grape wine, barley beer, and mead.

Gravesites typically yield a wealth of information. Since Neolithic times, people have been buried with food for the afterlife. Less often, people are buried in food. In a prehistoric Iron Age (500 B.C.E. to 500 C.E.) cemetery at Noen U-Loke in northeast Thailand, archaeologists found a huge sample of carbonized rice, much used in burials, “rice beds” in which some citizens were laid to rest on layers of rice, and then covered over with more. Finally, the “bed” was set on fire to purify the grave. Rice burials have been found nowhere else in the world. Since these graves also contain lavish jewelry and bronze goods, they indicate that the burial practice was reserved for those of special rank. It can be also deduced that the community produced a tremendous rice surplus under the distribution control of a chieftain, who wielded power over the rice farmers or producers.

Also of interest are containers in which food was stored and shipped. Often these were clay jars known as amphorae, ubiquitous throughout the ancient world for

The recovery of food from archeological sites is one of the most challenging of all tasks due to the fragile nature of the remains. The stakes are raised when the food is buried in jars under the sea, as in the case of these Phoenician amphorae that sank with a ship during a storm about 750 B.C.E. off the coast of what is now Israel. Vestiges of the contents proved that the amphorae once held wine. They are shown here in an underwater photo released by *National Geographic* in 1999. © AFP/CORBIS

carrying olive oil, fish sauce, olives, fruit, and wine. Excavation at the fortress Masada in Israel has turned up Roman amphorae with wine residues bearing the inscription “For Herod of Judea” (73–4, r. 37–4, B.C.E.), indicating that this potentate favored Italian vineyards.

Another aspect of food archaeology is culinary archaeology, the study of food preparation and utensils. Rice steamers have been recovered from Noen-U Loke in Thailand and other locations. Sophisticated techniques even make it possible to identify the temperature at which an ancient meal was cooked. When Lindow Man, a body discovered in a British bog, was retrieved, the charred bran-and-chaff stomach contents were subjected to electron spin resonance, capable of measuring the highest temperature to which a material has been subjected and for what length of time. The conclusion: the meal was probably a griddle cake, cooked on a flat, heated surface for about half an hour at 392°F (200°C).

### Preserved Meals

Occasionally, archaeologists unearth actual charred meals, most notably at Pompeii and Herculaneum, covered by ash when Mt. Vesuvius erupted in 79 C.E. There, inhabitants left complete meals on tables, food in shops, and loaves of bread in bakery ovens. The Egyptian priests at the Temple of Isis in Pompeii were eating a meal of fish and eggs when the eruption occurred. Researchers at Pompeii have taken their work a step further to investigate how the Romans, master urban planners, incorporated growing, processing, distribution, and storage of food and drink into the city layout. By measuring distances from dwellings to restaurants and bakeries, they

can determine how far a citizen had to travel to quench his thirst or get something to eat.

After excavating artifacts (manmade objects) and subjecting them to laboratory analysis, the broader task is to document processes of cultural change such as the beginning of agriculture in a particular area. Food plays a critical role in the development of civilization and culture. The problem of subsistence must always be solved first before a food surplus can be generated, the population expands, and there are the beginnings of a ranked society with some elite members engaging in ruling, military activities, directing religion, and craft making. It is food that propels the development of ever more complex societies.

**FOOD AS A WEAPON OF WAR.** Providing or withholding food during times of conflict can be just as potent a weapon as the guns, bombs, and explosives of opposing armies. Control of food supplies during war is important because wars disrupt the seasonal pattern of growing crops, displace farming populations, and prevent the transport of food within the area of conflict. The economic costs of war may so impoverish citizens and local governments that they are unable to purchase or distribute needed food, even if it is available. A major focus of the Marshall Plan for Europe after the Second World War was to prevent the kind of starvation and social upheaval that had followed World War I. More recent re-

lief efforts have focused on distributing food to refugees of many regional conflicts, where imposed famine was part of the combatants' military strategy in countries like Liberia, Mozambique, Somalia, and Sudan.

#### Withholding Food

Food can be withheld by preventing it from being grown and harvested, by destroying it after harvest, by preventing it from being shipped to where it is needed, or by contaminating it and rendering it unfit for consumption. Indigenous farming populations have been scattered or exiled from their native lands by conquering armies to make room for their own colonists who would subjugate and establish their hegemony over the local inhabitants, and provide food and warriors for future campaigns. Ancient armies have "salted the earth" and destroyed irrigation systems to make an area unsuitable for growing crops. In the culmination of the Punic Wars with Carthage in the third and second centuries B.C.E., Rome defeated the armies of Hannibal, destroyed his empire, and ploughed the land with salt to make it infertile. The Roman practice of contaminating water supplies by dumping dead animals into wells has continued into recent history as demonstrated by an instance during the American Civil War when Confederate soldiers fouled the water supplies of Union forces with dead animals. There are no instances of widespread contamination of food during war in the modern era, perhaps because of the universal condemnation of such practices by all civilized nations. Sieges of fortified positions have been used since time immemorial to starve, demoralize, and physically weaken the ensconced combatants. Pictorial representations in Egypt depict sieges over 4,000 years ago, while the *Iliad* of Homer describes the siege of Troy by the Greeks over 3,000 years ago. It, like many of the numerous sieges that followed, ended not through force of arms, but through deception and treachery. The Spartan siege of Athens that ended the Peloponnesian Wars (431–404 B.C.E.) was ineffective as long as Athens could obtain food by sea. Only by allying themselves with Persia and destroying the Athenian navy were the Spartans able to starve them into submission. A similar maritime strategy was employed, but in reverse, by Emperor Leo III of the Eastern Roman Empire, whose forces destroyed the Arab navy, maintained food imports, and broke their siege of Constantinople in 717. Sieges often do not work because the besieged forces have stored or can obtain enough food for the duration, or because the invading forces cannot obtain enough food or maintain their supply lines because of the surrounding hostile population.

A continuing problem with siege warfare was that the attackers could run out of food or succumb to disease in their unhealthy encampments. For this reason, the parties of siege warfare in the medieval West often agreed on a time limit, after which the besieged forces could leave without penalty. Such civility was rare even then, and certainly has not persisted to modern times of

total war. Parisians were reduced to eating rats during the siege that ended the 1870 Franco-Prussian War, and over a million Russians starved to death during the 500-day siege of Leningrad in World War II; more civilians died in Leningrad than in the bombings of Hamburg, Dresden, Tokyo, Hiroshima, and Nagasaki combined.

In modern times, sieges have expanded and evolved into embargos of critical war materials (for example, food, medicine, oil, strategic metals, technology, etc.) by nation-states. England imposed an embargo by sea for that area of Europe occupied by Napoleon, and Germany tried to embargo food and war materials to England and Russia by the United States in the Second World War. While food is now usually not embargoed for humanitarian reasons by the major powers, economic sanctions remain an implement of international policy and genocidal starvation as accepted strategy in some regional conflicts.

### Scorched Earth

Many countries have adopted a “scorched earth” policy (destroying anything that might be of use to an invading enemy) to prevent an invading army from living off the land. Both attackers and defenders in conventional wars and guerrilla struggles have used this strategy. During the U.S. Civil War, General William T. Sherman brought “total war” to the heart of the Confederacy by his infamous “March to the Sea” across Georgia and South Carolina, a scorched earth policy that is still debated as being barbarous or sound military strategy. The British used a scorched earth policy during their war with the Boers in South Africa, and the French conquest of Algeria (1830 to 1844) used it to starve the natives into submission. Unless ruthlessly enforced, it is often difficult to convince people to destroy all they have in advance of an invading force. The conquest of Gaul by Julius Caesar was almost prevented by this tactic, but Vercingetorix’s guerrilla campaigns were ineffective because he could not persuade his countrymen to adopt this painful policy wholeheartedly.

Russia very effectively used a scorched earth policy during its invasion by Swedish armies in 1709, Napoleon’s armies in 1812, and Hitler’s armies in 1941. Because the Russians removed most of the food and crops in advance, Napoleon’s half-a-million-man army could not live off the land as they had in previous campaigns. Despite being able to capture Moscow, they were too emaciated to hold it and had to retreat. The inability to find food locally also created severe problems for the German military in World War II, which was trying to feed three million soldiers. Forests, stores and transports were set afire; all grain and millions of cattle were shipped from the Ukraine to Russia, leaving nothing for the advancing German armies. However, nothing was left for the peasants who were equally bereft of food and shelter. As the Germans retreated towards Berlin, they too implemented a scorched earth policy to slow the pursuing Russian army.

### Providing Food

Since, as Napoleon is quoted as saying, “An army marches on its stomach,” procuring enough food to support an army in the field is a paramount concern for all commanders. Although weapons, clothing, and shelter are of the greatest immediate importance to soldiers, logistical support to provide food and material is often the decisive element in winning wars. Soldiers often had to truly “live off the land” even when in permanent garrisons or semipermanent encampments during lengthy sieges. Improvements in food preservation, packaging, and transportation have made modern armies immune to local vagaries in the availability of food.

The technologies of canning, freezing, dehydrating, and irradiating food were greatly advanced by the necessities of war. In 1795 Nicholas Appert, a French chef, won a prize offered by Napoleon for a way to prevent military food supplies from spoiling. By 1806, Appert’s principles for canning meats and vegetables in jars had been successfully applied to the canning of meat, vegetables, fruit, and even milk for the French Navy. The English adopted the process to use with metal containers in 1810, and when Napoleon faced Wellington at Waterloo in 1815, both of their troops ate canned rations.

Frozen foods had been around since the 1920s, but did not become important until they were used to feed U.S. troops overseas during the Second World War. At home, frozen foods caught on with American consumers because canned foods required precious metal and were rationed, while frozen foods were not. Dehydration has been practiced for millennia by peoples who dried grasses, herbs, roots, berries, and meats by setting them out in the sun. Dehydrated foods are important for the military because of their light weight and minimal volume. During World War II, the U.S. Army tested irradiation on fruits, vegetables, dairy products, and meat. Irradiated food has been pioneered and extensively used since the 1960s by the military and NASA. The responsibility to feed large numbers of people on military bases and on the battlefield, and its enforced administrated structure provides an excellent opportunity for large-scale testing of new food-handling and preparation technologies by the military. Coupled with the mandated desires of the U.S. Congress for the military to eat domestically grown food, even in distant military operations, and the realities of combat, many food-handling technologies have been first implemented by the military before they gained widespread acceptance by civilians.

**FOOD BANKS.** Warehouses that collect and store donations of surplus foods, food banks distribute the foodstuffs to authorized nonprofit organizations that provide assistance to the needy. The food comes from many sources, including individual contributions, local food drives, regional grocery stores, farmers, food service companies, and national food corporations. The surpluses arise from mislabeling, mispackaging, mishandling, and other factors that contribute to loss of commercial value—however, all the foods are safe and edible.

Food banks began in the late 1960s when the retired Arizona businessman John Van Hengel volunteered in a soup kitchen and began to solicit donations of food products that would otherwise be wasted. When the soup kitchen received more food than it could handle, Van Hengel set up a warehouse to store and distribute these food products. As other cities learned of the food bank concept, they began to duplicate it in their areas. A grant from the federal government in 1976 assisted the development of food banks throughout the nation. Although food banks developed as temporary emergency food relief organizations, they have become permanent fixtures

in America because of economic recessions, job insecurity, erosion of public assistance benefits, and sharp increases in housing and other costs. Food banks multiplied from a few dozen in the 1980s to over 250 in 2002.

Today, approximately 80 percent of all food banks in the United States are networked through an organization called America's Second Harvest, which is the largest domestic hunger relief organization. Food banks have the capacity to receive large volumes of food and distribute it efficiently and quickly. America's Second Harvest serves as a link between food banks in its network, and can assist with moving food out of one bank and into another (thus helping to control inventory), move product quickly, and minimize waste. The banks are typically operated by a small staff of employees who direct the program, manage the warehouse operation, and oversee a large corps of volunteers. Financial records are kept and the banks are audited annually. Food banks must comply with local health codes regarding sanitation and safe food handling. Because of the Tax Reform Act of 1976, corporate donors can take advantage of tax deductions for their contributions—not only for 100 percent of production costs, but also for 50 percent of the difference between the product cost and the normal sale price. As a result of the Good Samaritan Act passed by Congress in 1981, donors are absolved from liability for the food's safety as long as they make an effort to determine that the food is edible and fit for human consumption when donated.

The funding for food banks comes from private contributions, foundations, some government sources, and fund-raising. The organizations that receive the food are also charged what is called a shared maintenance fee. This is a small amount (18 cents per pound in 2002) to help cover the cost of handling the product, and is not based on the value of the food. Grant monies are often available to those organizations that cannot afford even this small fee. Very perishable food items are sometimes given away at no cost as they cannot be stored for long periods of time.

Large food bank operations have developed innovative ways to distribute even more food. The food banks in Delaware and Washington, D.C., operate onsite community kitchens where donated foods are prepared into meals that can be distributed to programs such as the Kids Café, which is an after-school feeding program for low-income children.

Food banks collectively distribute nearly a billion pounds of food annually, feeding more than 23 million needy Americans, including 8 million children and 4 million senior citizens. As the problem of hunger in America continues to grow, low-income families will continue to rely on food banks to provide a source of low-cost food assistance and a means of decreasing their food insecurity.

Hunger and poverty go hand-in-hand, and the poor will always exist in every society. While food banks cannot eliminate poverty, their mission is to abolish hunger;

## FOOD CONSUMPTION SURVEYS IN THE UNITED STATES

Since the 1930s, food consumption surveys have been carried out by the U.S. Department of Agriculture (USDA). After small-scale studies, nationwide monitoring began in the 1950s. In 1955 the Household Food Consumption Survey, which was first based on a representative sample of households, was initiated. The survey investigated food use on the household level. Beginning in 1965, a component of individual dietary assessment has been included in the National Food Surveys. Since 1985, household consumption has been replaced by the Continuing Survey of Food Intakes by Individuals, which is based on dietary assessment through twenty-four-hour dietary recalls. Since the late 1980s, food surveys have been combined with the Diet and Health Knowledge Behavior Survey (DHKS). Knowledge and attitudes toward diet as well as dietary behavior are assessed to improve understanding of individual dietary patterns.

they do an admirable job of it, providing assistance to nearly a tenth of the population. They augment the many federal food assistance programs that play the larger role in the food-security safety net for limited-income families. Unfortunately, it does not look as if food banks will disappear from America as their founders had once hoped. The United States produces enough food to adequately feed all of its citizens. The problem is often getting the food to those who need it; food banks are one solution.

**FOOD CONSUMPTION SURVEYS.** Food consumption surveys—sometimes referred to as food intake surveys or dietary surveys—monitor food use by data collection at three different levels. On the national level, food availability may be described by supply data such as food balance sheets. These results express food availability rather than food consumption in a nation and are not further discussed here. The second type of food consumption survey measures food use within a household, and the third type assesses individual intake of foods and beverages. These latter two survey types collect information on kinds, amounts, and frequencies of food consumption and occasionally on expenditure for food purchases. Furthermore, these surveys include information on factors influencing food intake patterns such as socioeconomic criteria, food perceptions, and beliefs.

At the beginning of the twentieth century, the investigation of food consumption patterns became necessary in order to identify inadequate and insufficient diets in parts of the population. This was especially important among urban industrial workers for whom mass production of food was needed because they no longer had ready access to farm produce. The first small-scale studies were carried out in different countries. As the number of participants in such surveys increased, the scope widened to include health issues related to food consumption. To

gain up-to-date information, these surveys were repeated on a regular basis. Advanced sampling techniques enabled researchers to design representative surveys.

Methods and materials of data collection are selected in accordance with the objectives of the survey. If the household is the focus, food inventories and household accounts are used to collect data on present food use, while food-list recalls monitor food use in the past. Food consumed outside of the home and the food distribution among household members are not assessed. Results are expressed in quantities of food consumed, expenditures for food purchases, and energy or nutrient availability per household. Comparisons of food availability in households among different communities or socioeconomic groups can be made. Dietary changes in a total population or subgroups of a population can be investigated.

The method for assessing individuals' dietary intake is the food record. Quantities are either accurately weighed or estimated by household measures. The twenty-four-hour recall assesses food intake during the previous day while diet histories focus on usual dietary patterns in the past. Food Frequencies Questionnaires (FFQ) ask how often food items are usually consumed within a defined period. The questionnaires and the diet histories focus on long-term subjective perception while food records and twenty-four-hour recalls are suitable for investigating absolute or relative nutrient intakes of groups and individuals.

TABLE 1

Dietary assessment methods		
Method	Period	Features
Food record	Present diet	Quantities and kinds of foods Time and location of consumption Presence of fellow eaters
Twenty-four-hour recall	Last 24 hours	Quantities and kinds of foods Time and location of consumption Presence of fellow eaters
Diet history	Last month(s)	Meals usually consumed Dishes and foods usually consumed
Food frequency questionnaire	Last weeks or months	Food list provided Frequency of consumption of food items Quantities, e.g., portion sizes

With assistance from food composition tables or data banks, energy and nutrient intakes are estimated. Thus quantities and qualities of diets as well as nutrient intakes of groups or individuals are monitored. Some surveys focus on specific target groups—for example, age groups (such as infants or elderly persons) or individuals with particular diets, conditions, or diseases such as pregnancy or diabetes, or on selected food groups (for example, fruits and vegetables).

Food and nutritional planning on the national or international level is based on these data sources, as are estimates of the adequacy of dietary intakes of population groups. The development and evaluation of educational programs is based on these results. The relationship of diet and health status as well as estimates of average intakes of additives and contaminants are other important issues.

The main limitation of food consumption surveys is that they depend on accurate report or recall of food quantity and type by the participants in the study. The quality of nutrient and energy values depends on the quality and accuracy of food consumption tables.

**FOOD COOPERATIVES.** Food cooperatives represent a particular subset of a larger environment of cooperative businesses. Cooperative business enterprises are primarily distinguished from other forms of business organization by the fact that their members consider other goals to be more important than return on invested capital. In its Statement of Identity, the International Cooperative Alliance defines a cooperative as "an autonomous association of persons united voluntarily to meet their common economic, social and cultural needs and aspirations through a jointly-owned and democratically-controlled enterprise."

Several characteristics commonly typify a cooperative enterprise. These characteristics, based on values that are made explicit to (and by) their members, include:

Autonomy: the cooperative is as independent of government and private enterprise as possible;

- Association of persons: the definition deliberately does not read an “association of individuals”;
- Voluntary: members are free to join and leave at will, within the purposes and resources of the cooperative;
- Meet needs: the central purpose of the cooperative is to meet member needs, which can be purely economic or social and cultural;
- Joint ownership and democratic control: the members own the cooperative on a mutual basis. Decisions are made democratically by the members and are not controlled by capital or by government;
- Enterprise: the cooperative is an organized entity that typically functions in the marketplace and engages in the exchange of goods and services.

There are over three hundred food cooperatives in the United States today. Through food cooperatives, consumers have sought to improve the quality and nutrition of available foods, to become better educated about food and environmental issues as they pertain to food choice, and to create a marketplace for organically grown foods. Food cooperatives often have mission statements that support such goals. For example, Puget Consumers Cooperative, based in Seattle, Washington (the largest food cooperative in the United States) has as its mission statement, “to provide the highest quality natural foods and products. We create and cultivate the marketplace for locally grown and organic products and are a vital community resource on food, nutrition and environmental issues.”

## History

The concept of cooperation germinated in the middle 1800s during the early period of industrialization. A small group of weavers in Rochdale Village, England, is considered to be the first practical application of the concept. There, in 1844, twenty-eight weavers combined their skills and ambitions, agreeing to share the burdens and rewards of a self-supporting economic colony. Other examples of co-ops appeared in the late 1800s throughout England and Europe, particularly in Finland.

It is not clear which consumer co-op in the United States was the first. According to one source, it was a buying club for household supplies created in 1844. Another source claims that the first consumer cooperative in the United States was established in Philadelphia in 1862. Whichever was actually the “first,” the popularity of consumer cooperatives has tended to increase in waves coincident with periods of economic decline (the Great Depression) and political and consumer unrest (the 1960s). What is now referred to as the “old wave” of growth in the number of cooperatives in the 1930s was inspired largely by economic depression. The cooperative was viewed by the Hoover and Roosevelt administrations as an “American concept” and as a solution to the suffering farming industry. But with the improved

war-oriented economy of the 1940s, support waned for co-ops and the philosophies that went with them. The impetus for the most recent expansion (the “new wave”) of American cooperatives in the relatively prosperous 1960s lay in a desire to harness and enhance social capital, build community, and achieve local autonomy from an increasingly global food system. In the 1960s and 1970s in the United States, food cooperatives were viewed as a political as well as economic alternative to conventional supermarkets.

## Co-Op Values and Principles

From the earliest days of the Rochdale Pioneers, food cooperatives have emphasized the importance of honest dealings in the marketplace: accurate measurements, reliable quality, and fair prices. Members have insisted that their co-op have honest dealings with them. Ideally, this has led to honest dealings with nonmembers and a unique level of openness throughout the organization.

Since its creation in 1895, the International Cooperative Alliance (ICA) has been recognized as the authority for defining cooperatives and for determining the underlying principles that provide motivation for such enterprises. One of the major purposes of the ICA is to “promote and protect cooperative values and principles.”

Three formal statements of the cooperative principles have been made by the ICA—in 1937, 1966, and 1995. Each statement was carefully crafted to adopt and explain principles that were both relevant to and of value for the contemporary world. The latest statement of principles reflects substantial changes in the global economy, in international political alignments, in the economic development of Asia, Africa and Latin America, and in the worldwide human condition. These changes brought new challenges and opportunities to cooperatives worldwide. Some traditional cooperative assumptions were challenged, giving rise to new interpretations of cooperative values and inspiring a reconsideration of the role of cooperative enterprise in the twenty-first century and in societies undergoing rapid change.

**Cooperative values.** Cooperative values reflect convictions that these enterprises hold about how to achieve a better society and what form that society should take. Common values among food co-ops include: *Self-help*: People have the will and the capability to improve their destiny peacefully through joint action, which can be more powerful than individual effort, particularly through collective action in the market. *Democracy*: Members have the right to participate, to be informed, to be heard and to be involved in making decisions. Members are the source of all authority in the cooperative. *Equality*: Equal rights and opportunities for people to participate democratically will improve the use of society’s resources and foster mutuality, understanding, and solidarity. *Equity*: Fair distribution of income and power in society and its economic life should be based on labor,

not ownership of capital. *Solidarity*: Cooperatives are based on the assumption that there is strength in mutual self-help and that the cooperative has a collective responsibility for the well-being of its members.

**The 1995 cooperative principles.** Principles are guidelines for putting ideals and values into practice. If successful, principles are incorporated into the organizational culture of the cooperative; they are the broad vision statement for cooperatives and cooperators individually and collectively.

Seven ICA principles (revised from the 1966 statement and adopted in 1995) in abbreviated form are:

1. **Voluntary and Open Membership:** Cooperatives are voluntary organizations, open to all persons able to use their services and willing to accept the responsibilities of membership, without gender, social, racial, political or religious discrimination.

Participation as active and responsible members should be based on a clear understanding of the values for which cooperatives stand and on support for those values.

2. **Democratic Member Control:** Cooperatives are democratic organizations controlled by their members, who actively participate in setting policies and decision-making. Members of these societies should enjoy equal voting rights (one member, one vote) and participation in decisions affecting their societies.
3. **Member Economic Participation:** The economic benefits arising out of the operations of a society belong to the members of that society and should be distributed in such a manner as to avoid one member gaining at the expense of others. This may be accomplished by the following means: (a) by provision for development of the cooperative's business; (b) by provision of common services; or (c) by distribution among members in proportion to their transactions with the society.
4. **Autonomy and Independence:** This principle emphasizes that cooperatives must be free of intervention from governments or other sources so that ultimately the members are able to control their own destiny.
5. **Education, Training, and Information:** Education is a priority in cooperative enterprises. Education here is meant to be more than advertising products or distributing information. Rather, it means engaging the minds of members, elected leaders, managers, and employees of food co-ops in critical thinking regarding food, nutrition, health, and the food system.
6. **Cooperation among Cooperatives:** All cooperative enterprises, in order to best serve the interests of their members and their communities, should actively cooperate in every practical way with other cooperatives at local, national, and international levels.

7. **Concern for Community:** Grounded in the values of social responsibility and caring for others, this principle (added in the 1995 revision of ICA principles) articulates an interest in making contributions to a better society at large. By taking ownership over portions of the economy, cooperative members are saying, in effect, we can meet our needs and the needs of others better than they are currently being met. Because the effort is a mutual one, cooperative members understand that to provide for any member is to provide for all members.

### **The Food Co-Op Shopper**

Consumer research conducted in the 1970s, 1980s, and 1990s indicated important differences between food cooperative shoppers and their supermarket counterparts. Areas of difference included food-related behaviors; attitudes toward food and food safety, health, nutrition, and the food system; and political views. Food-related behaviors studied included dietary patterns and cooking habits. Food co-op shoppers were shown to buy items such as tofu, brown rice, alfalfa sprouts, honey, dried beans, yogurt, granola, and spinach with greater frequency than supermarket shoppers. Supermarket shoppers, on the other hand, tended to consume franks, beef, poultry, pork, white bread, white rice, candy bars, and potatoes with more frequency than co-op shoppers. Food co-op shoppers tended to have a greater enjoyment of cooking and to cook "from scratch" more often than the general population. This is consistent with a strong skepticism toward heavily processed foods associated with food co-op shoppers, particularly in the 1970s and early 1980s.

Environmental concern and concern over food system issues such as globalization, genetic engineering, and corporatization are more meaningful to food co-op members than nonmembers. Co-op shoppers also tend to put relatively less importance on year-round availability of produce items.

Over the years, consumers have been motivated by several factors to join and shop at food co-ops. Research from the 1970s suggests that lower prices, availability of natural foods, and product quality were dominant motivating factors for joining a food cooperative. Support for co-op values, economic and ecological interests, freshness of the food, the availability of locally grown food, social atmosphere, variety of products, and the availability of bulk items are additional motivators for co-op shoppers.

The growth of food cooperative membership observed in the 1970s and 1980s is thought to stem in part from concerns about food safety and the impacts processed foods may have on health as well as an increasing awareness of the diet and health relationship. The use of whole and organic foods among coop shoppers may be related more to the desire to decrease control of large companies and food processors and a sense

Women making pasta at a women's cooperative in Walata, Mauritania. © JUAN ECHEVERRIA/CORBIS.

of increased personal responsibility than to the nutritional value of such products. Access to bulk items, herbs and spices, organic foods, farm-fresh eggs and preservative-free bread were incentives for shopping at the cooperative. Co-op shoppers believed that organically grown foods possess beneficial nutritional attributes, and they were willing to pay a higher price for them. This preference was largely motivated by a belief that pesticide residues in foods posed a health risk. They also felt that there are environmental factors other than food processing that are harmful to health and to the environment.

### Establishing a Niche

From their beginning, consumer food co-ops have distinguished themselves from traditional food retailing by establishing active consumer education programs designed to increase awareness and understanding not only of food composition, but of the source of food and the production methods used. Co-op policies often reflect the values related to food and the marketplace that members consider to be important, such as a diverse product line that emphasizes quality, nutrition, and organic growing methods, health and nutrition awareness through education of members and staff, and shared participation by the staff in co-op decision-making.

Goals common to most food cooperatives include democracy, member education and participation, and a dedication to “pure” or “natural” foods. The latter goal in particular created the expectation that food cooperatives were places where natural foods could be found, and further defined the niche of these retail outlets. However, the demand for natural and organically grown foods

is increasing dramatically, and shoppers are able to find these foods in a wide range of retail and wholesale food outlets.

### Modern Trends

Food cooperatives continue to constitute a very small proportion of the food-retailing segment. As the availability of organic produce and multi-ingredient processed products has expanded throughout the food-retailing industry, and as supermarket chains have initiated active consumer education programs, the characteristics that distinguish food cooperatives as unique alternatives have become less clear. Expanded availability of “whole foods” and certified organic foods means that food cooperatives are no longer exclusive sources for these choices. However, these food-retailing enterprises may still provide important alternatives to supermarket chains. For example, food cooperatives still provide a space for debating agriculture and food system trends that is difficult to find in other institutions. Decisions about inventory are based less on market demand than on established goals, values, politics, and principles. Also, cooperatives still provide an atmosphere of community that is not found in more conventional supermarkets and megastores. In the past, food cooperatives have been innovators in the marketplace in the areas of unit pricing, consumer protection, and nutritional labeling. They may offer innovations in the future that are adopted throughout the retail industry. Finally, recent trends in food retailing in the United States and elsewhere may serve to renew interest and participation in food cooperatives. Food retailing, like agricultural production before it, is increasingly concentrated. Warehouse food stores and mass retailers with

grocery sections are gaining market share in some of the most profitable categories of food products and capturing the food expenditure of families with children, who comprise the most lucrative segment of the shopping public. This threat to the traditional grocery store may provide an opportunity for food cooperatives to offer an alternative food store that, by their very nature, are resistant to such trends.

**FOOD PANTRIES.** What are known as emergency feeding organizations in the United States include food banks, food pantries, soup kitchens, and shelters operated by nonprofit organizations and faith-based agencies. The emergency food assistance network provides food to people who lack the resources to obtain adequate amounts of food through conventional means. Food banks solicit donations of surplus or salvage food that they distribute to food pantries (which provide emergency grocery packages), soup kitchens and shelters (which provide on-site meals), and other feeding programs. Although religious organizations and nonprofit agencies have historically distributed food and meals to people in need, the sharp increases in such requests beginning in the 1980s associated with high unemployment, cuts in the social safety net, decline in the value of public assistance benefits, and increases in housing and other costs led to a proliferation of food pantries, soup kitchens, and government programs that defined hunger and homelessness as temporary "emergency" problems.

In 2001 the America's Second Harvest provider network included approximately 26,300 food pantries in the

United States, three-quarters of which are run by faith-based agencies affiliated with churches, mosques, synagogues, and other religious organizations. These food pantries received more than half (59 percent) of the food they distributed from food banks, with religious organizations, direct purchases, and federal government commodity programs supplying the remainder. More than 90 percent of these food pantries use volunteer staff, and many rely entirely on volunteers. Only 33 percent of the pantry programs have any paid staff.

Food pantries, also known as food closets, food shelves, or grocery programs, distribute nonprepared foods and other grocery items to needy clients, who then prepare and use these items where they live. In the United States, food pantries are primarily operated through referral systems, in which trained staff at nonprofit organizations screen clients and refer them to pantries operated by volunteers. The majority of food pantries prebag the food distributed to clients, while others allow clients to select their own food "grocery-store style." To the extent possible, pantries use several different factors, including household size, household composition (number of children, adults, elderly), and health status of household members, to determine the contents of a food order. Some follow nutritional guidelines in selecting prebagged items. On average, food pantries distribute food items to provide three meals per day per household member for three to five days. A sample list of items distributed to a single adult by a Pittsburgh, Pennsylvania, food pantry includes cereal, canned vegetables, Jell-o, juice, bread, canned beef stew, ground turkey, canned fruit, pasta, spaghetti sauce, and paper products. Some food pantries provide additional services. In 2001, 18.2 percent of the food pantries in the America's Second Harvest food provider network also provided nutrition counseling, 15 percent provided eligibility counseling for food stamps, 20.3 percent provided utility bill assistance, and 42.9 percent provided clothing assistance.

Many food pantries require that recipients run out of food prior to requesting assistance and categorize this condition as a food emergency. They also focus on serving clients compatible with their service mission and have much less need for documentation and much more trust in recipients' testimonies than government agencies. Only recently have U.S. food pantries begun to enforce explicit eligibility standards, such as income or residency, or require documentation of eligibility.

In the late twentieth century, the U.S. Conference of Mayors Task Force on Hunger and Homelessness surveyed the twenty largest American cities, revealing steady increases in demand for emergency food assistance, a rising proportion of those requesting food assistance who are families with children, more requests from working families and individuals, unmet demand for emergency food assistance, and numerous cities where food assistance facilities must turn people away. In 2001 more than half (59.8 percent) of the food pantries in America's Sec-

ond Harvest food provider network served more clients than they had in 1998. More than two-thirds (67.9 percent) of these pantries experienced problems related to funding, and about two-fifths (39 percent) had problems related to food supplies.

Government data indicate that at least 9.2 million households in the United States were food insecure in 1999 and that approximately 3 million households had experienced hunger at some point in that year. The food insecure households contained an estimated 27 million people, of whom 11 million were children (Andrews et al., 2000). The existence of large numbers of people without secure access to adequate nutritious food represents a serious national concern. An important response to this problem has been the growth of private sector institutions created to provide food for the needy.

Throughout the United States, food pantries, soup kitchens, and homeless shelters play a critical role in meeting the nutritional needs of America's low-income population. These organizations help meet the needs of people and households that otherwise would lack sufficient food. However, emergency feeding organizations are ultimately limited by the depth of the hunger problem, their reliance on volunteers, the availability of government and food industry surpluses, lack of legally enforceable rights for food recipients, and the discrepancies between where food providers are located and where those who need food live. Seeing these organizations as the primary solution to the problem of hunger diverts attention from the societal relationships that produce hunger, including economic restructuring, erosion of public assistance benefits, major cuts in social welfare programs, and high housing, medical, and other costs.

**FOOD POLITICS: UNITED STATES.** Food, the fuel of life and a source of lifelong pleasure, might seem to be the antithesis of politics, a term redolent of power, manipulation, and commerce, but the two are tightly linked. Commercial interests affect nearly every aspect of the systems of food production, distribution, and consumption, from farm to fork. The extraordinary size of the food enterprise and the vast sums at stake readily explain the ferocity of debates about dietary advice to the public, health claims on food package labels, regulations for meat safety, nutritional requirements for school meals, and labeling of genetically modified foods, to cite just a few examples. Debates over such issues derive from the disparate interests of the principal stakeholders in the food system, including the food industry and the consuming public of course but also government regulators, public health officials, and nutrition researchers and educators. Because all stakeholders should benefit from a food supply that is adequate, healthful, safe, environmentally sound, culturally appropriate, affordable, and delicious, the interests of these groups might appear to be congruent. The food industry, however, has an additional and compelling interest—to sell products. The conflict between the commercial interests of food companies and the widely varying concerns of other stakeholders is a principal reason why food issues are so controversial.

In this context the term “food industry” encompasses the full range of companies in the United States that produce, process, manufacture, sell, and serve foods, beverages, and dietary supplements (see the sidebar “The U.S. Food Industry”). Taken together the various sectors of this industry provide a food supply so plentiful, varied, relatively inexpensive, and devoid of dependence on geography or season that all but the poorest of Americans can obtain enough energy and nutrients to meet their biological needs. Indeed the U.S. food system as a whole—food produced in this country, plus imports, less exports—provides enough energy to meet the needs of every man, woman, and child in the country nearly twice over: 3,800 calories per capita per day. This amount is one-third higher than the caloric needs of most men, is twice the level needed by most women, and exceeds the requirements of babies, young children, and the sedentary elderly by even greater amounts. Even if, as the U.S. Department of Agriculture (USDA) estimates, 1,100 of those calories might be wasted (for example, in spoiled fruit or discarded oil for frying potatoes), the overabundance of food poses a major problem for the industry. It forces competition.

Because people, even those who overindulge, are limited in the number of calories they can consume, a choice of any one food means rejection of others. Thus food companies must convince people either to select their products over competitors' products or to consume more food overall, no matter how consumption or overconsumption might affect nutritional status or body weight. Food, beverage, supplement, and food service companies spend more

## THE U.S. FOOD INDUSTRY

The huge U.S. food industry is best understood in sectors. The agribusiness sector raises food crops and animals and makes and sells fertilizer, pesticides, seeds, and feed. Other sectors sell machinery, labor, real estate, and financial services to farmers or transport, store, distribute, export, process, and market foods after they leave the farm. The food service sector includes restaurants, fast food outlets, and bars but also service by institutions, such as schools, hospitals, prisons, and workplaces, and by food carts and courts. The retail sector includes supermarkets, convenience stores, and vending machines. This vast food system generates nearly \$1 trillion in annual sales, accounts for nearly 15 percent of the U.S. gross national product, and employs 17 percent of the country's labor force. Of the more than \$800 billion or so that the public spent directly on food and drink in 2000, alcoholic beverages accounted for about \$100 billion. The rest was distributed among retail food enterprises (54 percent) and food service (46 percent).

Within this industry huge national and multinational corporations vie for control of production or sales of specific food commodities. In 1997, for example, just three companies, Philip Morris (Kraft General Foods and Miller Brewing), ConAgra, and RJR-Nabisco, accounted for nearly 20 percent of all food expenditures in the United States. In 2000 seven U.S. companies (Philip Morris, ConAgra, Mars, IBP, Sara Lee, Heinz, and Tyson Foods)

ranked among the ten largest food companies in the world and generated up to \$50 billion in sales annually. Others, such as Coca-Cola, McDonald's, PepsiCo, Procter and Gamble, and Roche (vitamins), ranked among the top one hundred worldwide. The nearly thirteen thousand outlets of McDonald's, the leading U.S. food service company, brought in about \$20 billion in sales in 2000, more than twice as much as its nearest competitor.

These companies and others introduce 10,000 to 15,000 new food and beverage products annually into a marketplace that already contains about 320,000 such items. These items must compete for supermarket shelf space; even the largest supermarkets have room for just 50,000 products. Of the 11,000 new products introduced in 1998, for example, more than two-thirds were condiments, candies and snacks, baked goods, soft drinks, and dairy products (cheese products and ice cream novelties), foods largely allocated to the top ("eat occasionally") section of the U.S. Department of Agriculture's 1992 Food Guide Pyramid. Slightly more than one-fourth of the products were "nutritionally enhanced" so they could be marketed as low in fat, cholesterol, salt, or sugar or as higher in fiber, calcium, or vitamins. Some enhanced products, among them no-fat cookies, vitamin-enriched cereals, and calcium-fortified juice drinks, contain so much sugar that they belong at the top of the pyramid even though they are marketed as "healthy."

than \$30 billion annually to promote their products to the public, and nearly 70 percent of this amount is applied to convenience foods, candy and snacks, alcoholic beverages, soft drinks, and desserts. In contrast, just over 2 percent is used to advertise foods considered more healthful, such as fruits, vegetables, grains, or beans. Furthermore the annual advertising expenditures for any single, nationally distributed food product are tenfold to fiftyfold higher than the total expenditures by government agencies to educate the public about food and nutrition.

The inequality of funding for dietary advice is only one aspect of U.S. food politics. Food companies also use the political system to convince Congress, government agency officials, food and nutrition experts, the media, and the public that their products promote health (or at least do no harm) and should not be subject to restrictive regulations. To protect their marketing environment, they contribute to congressional campaigns, lobby members of Congress and federal agencies, and when all else fails, engage in lawsuits. Nearly every food company is represented by a trade association or public relations

firm whose job is to promote a positive image of the company's product among consumers, professionals, and the media. The companies form partnerships and alliances with professional nutrition organizations, fund research on food and nutrition, sponsor professional journals and conferences, and make sure that influential groups, including federal officials, researchers, doctors, nurses, schoolteachers, and the media, will favor and not criticize their products. To distract attention from health, safety, or environmental concerns, they may argue that restrictive regulations overly involve the government in personal dietary choices and threaten constitutional guarantees of free speech.

Such actions are routine, legal, and thoroughly analogous to the political activities of any other major industry—tobacco, for example—in influencing health experts, federal agencies, and Congress. Promoting sales of food raises more complicated issues than promoting use of tobacco, however, in that food is required for life and causes health problems only when consumed inappropriately. Nevertheless the primary mission of food

## FOOD POLITICS IN ACTION

Two examples, dietary recommendations and trade disputes, illustrate the breadth of ways politics connect to food. Food guides and dietary guidelines sometimes advise restriction in one or another food or component. When they do, industries affected by the advice raise objections. In 1991, for example, the U.S. Department of Agriculture (USDA) cancelled publication of its Food Guide Pyramid. Producers of meat and dairy foods protested that the placement of their products in the triangular design of the pyramid conveyed an “eat less” message. In turn nutrition and health experts protested the cancellation, arguing that the pyramid design was fully supported by research. The USDA released the guide one year later, after investing nearly a million dollars in face-saving research and agreeing to several design changes favored by meat and dairy producers. In another incident in 2000 the committee developing national dietary guidelines suggested Americans “limit” sugar consumption, but federal agencies changed that word to “moderate” in response to pressures from sugar trade associations. Although sugar contributes calories but no nutrients to diets, the trade groups maintained that existing science did not justify recommendations to restrict sugar intake. Sugar producers famously contribute large sums of money to both political parties, and the agencies did

not want to do battle over so seemingly trivial a change in wording.

Trade disputes constitute an example of food politics on a global scale. The United States participates in a treaty with the World Trade Organization (WTO), an international body that sets standards for food safety and domestic farm subsidies. WTO rules are designed to prevent nations from instituting farm policies that might unfairly favor their ability to compete in world markets. In 2001 U.S. participation in the WTO came into conflict with long-standing policies that subsidize agricultural producers to protect them against price fluctuations. The most visible subsidies are price supports for sugar and milk, but taxpayers also support production and market quotas, import restrictions, and marketing and promotion programs for major food commodities. The total cost of such subsidies, most of which go to large agricultural corporations, exceeded \$32 billion in 2000. In 2001 at least eight members of Congress, five of whom held positions on committees that consider agricultural policies, personally received farm subsidies ranging from nearly \$40,000 to \$650,000 annually. In this situation the interests of agricultural producers and their congressional supporters directly conflict with U.S. foreign policy and raise political dilemmas that cannot easily be resolved.

companies, like that of tobacco companies, is to sell products. For this reason alone basic dietary advice to prevent disease by restricting consumption of saturated fat, sugar, salt, or alcohol or to prevent obesity by eating less food in general directly conflicts with the commercial interests of food companies. Similarly, concerns about pollution of air, water, and soil conflict with the economic interests of agricultural producers and giant chicken and hog operations.

Food and politics are connected in ways both great and small, as illustrated in the sidebar “Food Politics in Action.” As those examples demonstrate, food is a political issue. Overabundant food and its consequences occur in the context of increasing centralization and globalization of the food industry. Because food affects lives as well as livelihoods, almost any aspect of its production or consumption stimulates attention from interest groups and the public at large. Food issues inevitably involve struggles over the way the government balances corporate against public interests. Although all stakeholders have the same right to use the political system as do food companies, most others are motivated by health, safety, or environmental concerns rather than by profit,

and they rarely have equivalent resources. Nevertheless they sometimes achieve political objectives. In this manner struggles over food issues reflect and contribute to essential functions of the American political system.

**FOOD PRODUCTION, HISTORY OF.** Ensuring sufficient food supplies is one of the most basic challenges facing any human society. Organized and efficient food production supports population growth and the development of cities and towns, trade, and other essential elements of human progress.

For many thousands of years, people collected their food from the wild or hunted animals large and small. The teamwork required to bring down a mastodon may have been the first type of collective enterprise in which humans engaged. The “hunter-gatherer” mode was sufficient for small groups in favorable environments, but as population grew and people pushed into areas less endowed with easily obtainable food, they sought more reliable sources of nutrition.

Scientists believe that agriculture was established first in the Fertile Crescent of the Middle East about ten or eleven thousand years B.C.E. The region was home to a variety of edible and easily cultivated crops: wheat and barley among the cereal crops, and lentils, peas, and chickpeas among the vegetables. Also, the region was endowed with wild goats, sheep, pigs, and cattle, all of which were domesticated and became important sources of food. Cattle are also useful work animals, and all these animals produce manure for fertilizer. Thus, a complete agricultural package was available, and it helped give rise to the civilizations in the Middle East. The need for common facilities to thresh and store grain was a major impetus for settlements; the wall of Jericho dates from around 8000 B.C.E. and was presumably built to protect its food supply.

Agriculture developed independently in the part of Mexico and Central America known as Mesoamerica; in the Andean highlands of Peru; in the American Midwest; in north and south China; and in Africa. But the Fertile Crescent had a long head start and the most favorable combination of plants and animals, and this eventually translated into a significant cultural advantage for Europe.

In the ancient world, the Mediterranean Sea was crisscrossed with ships carrying spices from the Middle East and ultimately India, wine and olive oil from Greece, and grain from Egypt. The city of Rome came to depend on wheat from Egypt and North Africa to supply the grain (and, later, bread) that was distributed free of charge

to its plebeians. The *annona* (the distribution of free or reduced-price grain or bread) reached impressive dimensions: by 350 B.C.E., an estimated 120,000 people received six half-pound loaves per day provided by 274 public bakeries. It was one of the world’s first examples of mass production of a specific food product.

Roman agriculture was otherwise centered on the *villa rustica*, a type of large estate with diversified production of grain, vegetables, fruits, nuts, and livestock. After the Roman Empire collapsed, these estates became the model of the medieval fief, the property held by a lord and worked by serfs who were legally bound to the land. The serfs had to work the lord’s land but also had the right to work strips of their own, plus small kitchen gardens. In the early feudal period, peasant families could gather game in the forests, but eventually these were reserved to the aristocracy and the peasants got by on little more than bread and gruel.

Technology, as simple as it was in the Middle Ages, played a role in increasing food production. The development of a heavy plow capable of breaking the dense,

Professional trade journals from the past provide rich source material for the history of food production. ROUGHWOOD COLLECTION.

This Australian photograph from the early 1890s records an old method of hand grading and packing apples. © BETTMANN/CORBIS.

wet soils of northern Europe reached Germany by the eighth century, and opened up a major new grain source for the rest of the continent. Grist mills powered by wind or water popped up all over Europe beginning in the eleventh century, providing large-scale processing of grain into flour.

Medieval European crop farmers had few options for increasing production. The usual practice was to rotate fields between grain and pasture so that they would be refreshed by animal manure between crops, a practice called “fallow.” In the later Middle Ages, the revitalizing power of legumes, which supply nitrogen to the soil, a technique lost since Roman times, was rediscovered. Rotating fields through grain, legumes, and fallows boosted productivity by at least a third and added peas, beans, chickpeas, lentils, and other vegetables to the European diet.

China, often thought of as a land of rice, also depended heavily on millet, wheat, and soybeans. Rice production increased significantly in the eleventh century when new strains were imported from Southeast Asia. Chinese fishermen also gathered fish from the ocean, lakes, and rivers, and sold them in vast central markets, which supplied networks of cookshops, restaurants, banqueting halls, and other eating places.

The Arab world also had a varied and sophisticated system of food production, with water-powered mills grinding grain full-time in North Africa and fishermen packing Mediterranean tuna in salt. The Arabs introduced citrus, rice, and sugarcane to Europe and controlled the lucrative spice trade with India. European

interest in breaking the Arab hold on the spice trade led to the voyages of discovery of Vasco da Gama and Columbus.

Discovery of the New World touched off the greatest and most rapid spread of new crops the world had seen. The Americas contributed maize (corn), potatoes, tomatoes, and peppers to Europe, while the Europeans brought wheat and other staple crops, and sugarcane, which was very successful in Brazil and later the Caribbean region. Sugarcane cultivation created a demand for labor that was met by the African slave trade. The “Columbian Exchange” thus laid the basis for much of the subsequent economic and political history of the New World.

In the Old World, the decline of feudalism and the rise of cities and towns helped move agriculture from subsistence to a market orientation. Land that had been held in common and used mainly for grazing was consolidated under the control of individual landowners, which greatly increased production of both crops and animals. The draining of marshy land, especially in England and the Low Countries, was accelerated. All these trends supported the more intensive cultivation of the available land and the production of more and cheaper food for growing and more urban populations. By 1700, European agriculture could provide approximately two-and-a-half times the yield per input of seed that had been normal in the Middle Ages (Roberts, 1997).

Science and technology played an increasingly important role in food production in the eighteenth and nineteenth centuries. The development of mineral and then chemical fertilizers freed farmers from reliance on manure and fallows as ways of renewing the soil. New equipment, such as the mechanical seed drill, made for more efficient planting. The mechanization of agriculture advanced rapidly in the nineteenth century with mechanical reapers, the tractor, and electric milking machines, among other innovations. Scientists also developed a better understanding of the nutritional components of food, which led to an emphasis on a balanced diet and, by the twentieth century, resulted in the improvement of food with the addition of vitamins and minerals to products such as bread and breakfast food.

Preserving food for later consumption has always been a challenge, especially in countries with long winters when little fresh food was available. Grain kept well if kept dry, but meat and fish had to be salted, and a monotonous diet of bread, dried peas, and salted fish sustained many Europeans through the winter until the early modern period. The preservation of food by heating it and sealing it in jars or cans began in the early nineteenth century, followed by pasteurization of wine and later milk to kill spoilage organisms. (The great chemist Louis Pasteur developed the process that bears his name to save the French wine industry, not its dairy farmers.) Canning and pasteurization made a wider variety of foods available to urban populations

With the development of steamships and refrigeration in the nineteenth century, the international food trade was transformed. Beef could be shipped from Argentina to England and bananas from Central America to New York. Worldwide food exports went from 4 million tons in the 1850s to 18 million tons thirty years later and 40 million tons by 1914 (Ponting, 1992). Chicago became the center of the U.S. meatpacking industry when refrigerated rail cars allowed packers to ship butchered meat virtually nationwide.

Agriculture, fisheries, and livestock and poultry production are now so efficient in Europe, North America, Australia, Argentina, Brazil, Japan, and other advanced countries that production can easily overwhelm demand, resulting in low prices and financial losses for producers. Governments all over the world subsidize their farmers and attempt to protect them from foreign competition, which keeps farmers in business but raises the cost of food to consumers. In the United States, for example, sugar costs twice what it does on the world market because of the protection of domestic producers.

Some of the benefits of Western agriculture and food production have been modified and transferred to the developing world. The use of high-yield wheat and rice, along with large doses of fertilizer—the so-called “Green Revolution”—has transformed the food picture in many countries. Wheat production in India nearly tripled from 1965 to 1980 while rice production increased 60 percent with the new strains and new methods. During the 1970s alone, rice production rose 37 percent in Indonesia and 40 percent in the Philippines.

Food today is often highly processed before being sold to consumers. Conversely, “pure,” “organic,” “all-natural” foods are becoming more popular. While dwarfed by the mainstream food industry, organic production can be profitable and viable. Governments seek to encourage this type of production, with strict regulations (effective 2003) on what can be labeled “organic” in the United States and programs such as “Label Rouge” (“red label”), which recognizes organic-style production, in France.

With rapid advances in biotechnology, genetic manipulation of crops accelerated in the 1990s and is expected to have a significant impact on food production. Maize, for example, is bioengineered to resist insect pests, and soybeans are modified to shrug off a common herbicide that keeps the fields free of weeds. These traits are advantageous to producers but not directly beneficial to consumers. The next level of genetic modification will be to insert traits actually beneficial to humans into food plants, such as rice fortified with extra vitamins that ward off blindness. Genetic modification of food plants is controversial and closely regulated by government but is felt by many to be the next frontier in food production.

**FOOD RIOTS.** A food riot can be defined as any gathering, whether planned or spontaneous, that may begin peacefully (a “food protest”) but evolves into disorder, leading to loss of control, violence, bodily harm, or damage to property. “Food riot” and “food protest” can be understood and discussed together as “food disturbances” (Gilje, p. 4). Food disturbances occur and have occurred for obvious reasons: When people feel their sense of entitlement to an adequate supply of food is being breached by those controlling the food supply, they will go to extreme measures to get the kind, quantity, and quality of food they feel they need for themselves and their families.

Historical and archaeological evidence documents the existence of food riots for several thousands of years and in all parts of the world, with periods of greater and lesser activity (Newman). Food riots occurred most frequently in the modern era (sixteenth through eighteenth centuries), declined through the nineteenth and twentieth centuries, and increased again toward the end of the twentieth century, primarily in developing countries.

#### Types of Food Riots

Since it is such a strong component and shaper of identity, food is deeply enmeshed in a collective as well as an individual sense of identity. How and why foods accrue special meaning—what makes them unique to particular groups of people—can vary widely: method of preparation, long-held tradition, particular “flavor principles,”

perception of purity, religious, cultural, or political significance, signification of wealth or status, or any combination of factors. The restriction in availability of foods imbued with distinctive meaning, then, whether through government manipulation or the vicissitudes of a “free market” economy, can function as a catalyst for collective protest. This is true not only in relatively isolated communities in the past, but in the ever-changing global villages of the twenty-first century.

A major subfield in social history, a rich body of scholarly work both documents and theorizes about food disturbances. European social historians especially have set the standard for scholarship in the field. While no two riots are ever exactly the same, and each contains a multiplicity of circumstances, historians have generalized that in the past food riots have fallen into three main categories: First, a blockage or entrave, where protesters blocked shipments of grain or other foodstuffs shipped from one region to another; second, the price riot or *taxation populaire*, where peasants seized the goods from a retail shop whose prices were deemed too high, which would then be sold for a “just price,” and often the money paid to the merchant. The final form of food riots, the market riot, was simply looting stores and supply depots to protest high prices or the lack of goods (Thompson; Gilje; Walton and Seddon).

Modern-day riots tend to conform to the latter category of market riots, as looting and destroying property are common factors. In addition are the more calculated, less volatile, demonstrations where the food at issue is ceremoniously dumped on the grounds of, for example, the local government headquarters. The boycotting of food, also a common means of protest in the twentieth century, can be effective, especially when centered on one item such as milk, beer, bread, or grapes, or on a single manufacturer (Linden). Boycotts, however, can evolve into full-fledged food riots if participants harass or vio-

lently attack those choosing to purchase a targeted item or frequent a targeted store.

### Theories of Food Rioting

Why do people riot over food? The obvious answer, that they riot because they are hungry, does not begin to answer the question since most who are poor and hungry do not riot. What intervening variables determine who eventually riots over which foods? Historians have analyzed and explained food riots in a variety of ways, including as collective action representing the “moral economy” of an era, as part of a so-called “female consciousness,” and as an exhibition of nationalism/patriotism. In his 1971 article, “The Moral Economy of the English Crowd in the Eighteenth Century,” eminent British historian E. P. Thompson sets about to provide a “thick description” of food rioters’ motives in preindustrial England, an era when subsistence riots happened with great frequency. Thompson argues that English peasant bread riots were symptomatic of a society caught between changing economic and political forces, of an England in the midst of moving from a looser collection of landed gentry to a stronger state, and from a mercantilist, feudal economic system to one of laissez-faire market capitalism. Peasants under the feudal system were used to bread sold at “just prices”—an amount reduced for the poor as part of the communal moral ethos. In the shift to an emerging market economy that abandoned the notion of the just price, peasants understandably clung to the older “moral economy.” Viewing inexpensive bread prices as an entitlement, when peasants felt the long-held social pact was not being honored under the new system, they rioted in response. People, argues Thompson, were thus not just rioting because they were hungry, but also out of a sense of injustice. As the peasantry evolved into the industrialized working class, conflicts over food were absorbed into and displaced by organized labor strikes. This explains why the number of food riots diminished considerably in the nineteenth century and beyond. Scholars have taken issue with Thompson’s moral economy theory, but few if any reject his theory outright.

Since women as well as men participated in food riots, often in unique ways, in recent years historians have employed gender as a category of analysis. While not disagreeing with the moral economists, historians such as Temma Kaplan point out that, although the number of food riots decreased in the nineteenth century, food disturbances nevertheless continued. Moreover, they argue, food rioting took on a noticeably female persona, in part because labor unions, the new locus of collective action, largely excluded women. Studying early-twentieth-century food riots in Barcelona, Kaplan argues that women participated in food riots as an extension of their role in the sexual division of labor: caring for home and family, which included food procurement and preparation. Women who accepted the traditional division of labor, argues Kaplan, could be radicalized to action in

the public sphere if they were prevented from fulfilling their obligation, especially the feeding and care of their families.

Food riots can also be examined in light of cultural meanings of consumption and their connection to nationalism. Historian Timothy Breen explores the relation between the growth of national consciousness and the American colonial rejection of British manufactured goods, including foodstuffs. Manufactured goods imported from Britain, readily available to so many people, Breen argues, resulted in a standardization of taste that transcended (to some extent) class boundaries. Consumer goods became politicized in the decades leading up to the American Revolution, providing a “shared language of consumption” that colonists of all regions and classes could understand and identify with, hence providing a common experience and knowledge base that united them enough to wage war against the mother country. While Breen does not limit his analysis to food but explores the meaning of consumer goods of all kinds, he focuses on the struggle over tea and its culminating food protest, the Boston Tea Party.

### Modern-Day Food Rioting

While food riots and protests have occurred in the nineteenth and twentieth centuries, the recent wave of food riots and protests are directly tied to strict economic austerity plans forced on developing countries by the International Monetary Fund (IMF) and other international banks. Governments attempting to repay bank loans must enact draconian measures, including abandoning the long tradition of subsidizing staple foods such as bread, rice, and cooking oil. The resulting high prices, deflated wages, scarce resources, shrinking food supplies, and empty bellies has led to a series of food riots, including the looting and pillaging of stores, fast-food restaurants, and supply depots, the blockading of farm and supply trucks, and protests in town squares that have erupted into mayhem and violence. Often the protests and riots have centered on one food item, usually a staple or key ingredient (often with a tradition of subsidization by the government) integral to the culture’s cuisine and consumed by rich and poor alike: rice, tortillas, onions, bread. The item, so central to their food habits, has functioned as a symbol of people’s intense frustration and anger at being trapped in a global economic web in which they seem to have no agency. Social scientists John Walton and David Seddon note similarities between these recent austerity riots and those of the preindustrial European peasantry. Each era of food rioting, they argue, includes a context of burgeoning urban metropolises, severe economic hardship, and populations with a strong sense of moral economy that regards subsidized food prices as a government obligation.

Amy Bentley

**FOOD SAFETY.** Food safety is a matter that affects anyone who eats food. Whether or not a person consciously thinks about food safety before eating a meal, a host of other people have thought about the safety of that food, from farmers to scientists to company presidents to federal government officials and public health officials. Ensuring the safety of food is a shared responsibility among producers, industry, government, and consumers. Safe food is food that is free not only from toxins, pesticides, and chemical and physical contaminants, but also from microbiological pathogens such as bacteria, parasites, and viruses that can cause illness.

Those working in the field of food safety are most concerned about microbial foodborne illness, a widespread but often unrecognized sickness that affects most people at one time or another. At least four factors are necessary for foodborne illness to occur: (1) a pathogen; (2) a food vehicle; (3) conditions that allow the pathogen to survive, reproduce, or produce a toxin; and (4) a susceptible person who ingests enough of the pathogen or its toxin to cause illness. The symptoms often are similar to those associated with the flu—nausea, vomiting, diarrhea, abdominal pain, fever, headache. Most people have experienced foodborne illness, even though they might not recognize it as such, instead blaming it on the stomach flu or a twenty-four-hour bug. Usually symptoms disappear within a few days, but in some cases there can be more long-lasting effects such as joint inflammation or kidney failure. In the most severe cases people die from foodborne illness.

Current estimates of foodborne illness in the United States are 76 million cases, 325,000 hospitalizations, and 5,194 deaths from foodborne pathogens per year. In cases when the pathogen is identified, bacteria cause 30 percent of foodborne illnesses, parasites 3 percent, and viruses 67 percent. But as far as deaths are concerned, bacterial pathogens are the leading cause of death, with 72 percent of total foodborne illness deaths attributable to bacteria. Fatality rates for two bacteria are particularly high; for *Listeria* 20 percent of the people may die, and for *Vibrio vulnificus* 39 percent. Just six pathogens account for over 90 percent of the deaths associated with foodborne illness: *Salmonella* (31 percent), *Listeria* (28 percent), *Toxoplasma* (21 percent), Norwalk-like viruses (7 percent), *Campylobacter* (5 percent), and *Escherichia coli* (3 percent). According to FoodNet data from 1996–1997, each person in the United States suffers 1.4 episodes of diarrhea per year. With a U.S. population of 267.7 million persons, that works out to 375 million episodes per year, many of them related to eating unsafe food. Factors that contributed the most to foodborne illness are improper holding temperatures, inadequate cooking, contaminated equipment, food from unsafe sources, and poor personal hygiene.

### Factors Influencing the Safety of Food

Stories of foodborne illness have become much more prevalent throughout the world. Is food less safe than it used to be, and if so, what factors account for this? News travels fast these days, both electronically and through the news media. What were once isolated events and stories, now reach millions within hours. Diagnostic techniques are constantly improving, allowing for identification of diseases, foodborne and otherwise, that would have been of unknown origin in the past. But even considering these facts, public-health officials believe that the risk of foodborne illness has increased over the past twenty years (GAO, 1996). Some threats to food safety have been around since ancient times, while others are newer, the result of changing demographics and lifestyles, production practices, and even evolution of microorganisms themselves.

### Demographics

The proportion of the population at serious risk of foodborne illness is increasing as the population ages and the number of people with weakened immune systems grows. People who are at higher risk of becoming seriously ill include infants, young children, the elderly, pregnant women, those taking certain medications, and those with diseases such as acquired immunodeficiency syndrome (AIDS), cancer, and diabetes that weaken their immune systems. Demographers predict that the proportion of people over sixty years old in industrialized countries such as the United States will rise from the current 17 percent of the population to 25 percent by 2025 (Kaferstein, 1999). In one survey, 89 percent of deaths with diarrhea as an underlying cause were adults fifty-five and over or children under the age of five (Morris, 1997).

While anybody can get sick from eating contaminated food, the severity of the illness depends on a number of factors. Most important among these are age, amount of contamination consumed, and health status of the individual. The body has a number of defenses to protect itself against harmful bacteria. The acidic gastric juices of the stomach are one of the first defenses against foodborne pathogens, as many bacteria cannot survive in an acidic environment. Very young infants and aging adults produce fewer, or less acidic, gastric juices than younger, healthy adults. The normal bacteria present in the gastrointestinal system form another protective barrier against foodborne illness by preventing harmful bacteria from colonizing the gut. Use of antibiotics, which destroy the protective bacteria normally present in the gastrointestinal tract as well as their target bacteria, make it easier for pathogenic bacteria to invade and cause illness. Finally, the human immune system, not fully developed at birth, gradually reaches maturity in puberty and then slowly begins to decline after about fifty years of age.

### Consumer Lifestyles and Demand

As the pace of life quickens, we often eat meals on the run, and spend less time on food preparation, preferring instead restaurants, convenience foods, or already prepared meals. This means that by the time you eat your food, it may have been transported, cooked, cooled, stored, transported again, reheated, and touched by numerous individuals. Each processing step introduces new hazards that could allow for the survival and growth of pathogens. In the United States, two out of three people ate their main meal away from home at least once a week in 1998. The typical consumer over eight years of age ate food away from home at least four times per week (Collins, 1997). Americans spend fifty cents of every food dollar on food prepared outside the home—from supermarkets, restaurants, or institutions.

Add to this the mishandling of food that occurs after a consumer purchases food and takes it home, and the likelihood of illness increases. Approximately 20 percent of reported foodborne illness cases occur from food cooked at home. Experts believe that this number is actually much higher, but that most people do not report cases of illness caused by foods cooked at home (Knabel, 1995; Doyle, 2000). As people cook less, they pass on less knowledge of cooking to their children, who are nevertheless increasingly responsible for preparing meals. This has grave implications for the future of food safety. In a survey of consumer food safety knowledge and practices, 86 percent of respondents knew that they should wash their hands before preparing food, but only 66 percent reported actually doing so. Only 67 percent of respondents reported washing or changing cutting boards after cutting raw meat or poultry. Older adults practiced safe behaviors more often than did younger adults (Altekruse, 1995). In an Australian study in which researchers asked

people about their food safety and kitchen habits, and then filmed them preparing food, there were large differences in what people said they did and what they actually did. Almost half the people who said they washed their hands after handling raw meat did not, and when they did it was often without soap. Nineteen percent of the households that claimed to have soap in the kitchen did not (Jay, 1999).

Consumers are increasingly demanding fresh and natural products, prepared with fewer preservatives. Without the traditional preservatives and processing methods that prevent microbial growth, modern all-natural and fresh products are more perishable. Food processing, mainly canning, freezing, and pasteurizing, not only extends the shelf-life of foods, but also inhibits bacterial growth, making food safer. As an example, fresh apple cider has been associated with several foodborne disease outbreaks. An outbreak of *Escherichia coli* O157:H7 in which a child died was associated with raw unpasteurized apple juice from a company that built its reputation on the naturalness of its products.

As the role of fresh fruits and vegetables in a nutritious diet has become evident, people are including them in their diet more. In 1993 Americans ate 27 percent more fresh produce than they did in 1973. An increase in the number of foodborne illness outbreaks associated with fresh produce has accompanied this increase in consumption. In the last twenty years of the twentieth century, the number of identifiable outbreaks in which produce was the food vehicle doubled (Tauxe et al., 1997). Most produce only grows in the United States in certain seasons, yet this seasonal availability has almost disappeared from our supermarkets as consumers demand year-round availability of produce. From 1996 to 1998 *Cyclospora cayetanensis* sickened more than 2,400 people throughout twenty states and Canada. The only common food vehicle among these individuals was raspberries imported from Guatemala. Smaller outbreaks of *Cyclospora* have been traced to basil and mesclun lettuce grown in the United States.

### Food Production and Economics

In the past, outbreaks of foodborne illness were relatively small and local. Illness could be traced back to local events such as weddings, church dinners, and other gatherings where a large number of people ate the same food. Today's food is produced in vastly different ways from those of even several decades ago. Food used to be grown, produced, and distributed on a local basis. Food production is now centralized and on a larger scale than in the past. Products made in a single processing plant in mass quantities are shipped all over the country, sometimes throughout the world. A mistake made in the processing will be felt nationwide instead of just locally. In 1994 an estimated 224,000 people throughout the nation became ill from *Salmonella enteritidis* after eating ice cream produced at one ice cream processing facility in Minnesota,

but shipped around the country (Hennessy, 1996). Recalls from processing plants are on a larger and larger scale. In 1998 Sara Lee recalled 35 million pounds of hot dogs and lunch meat due to the presence of *Listeria*. This is food contamination on a scale unprecedented a generation ago.

Even the manner in which farmers raise animals can contribute to an increase in food safety problems. A large number of animals are often crowded together, increasing their stress levels and weakening their immune systems. This crowding also facilitates the spread of disease from one animal to another. In the old days a sick animal would be fairly isolated and if it became sick it would not pass on illness to the rest of the flock or herd. But with closer animal-to-animal contact, disease can quickly spread throughout the whole group.

### New and Evolving Pathogens

As recently as fifty years ago scientists had identified four foodborne pathogens. Today five times that number are on the list. Twenty years ago scientists did not even recognize three of the four pathogens that the Centers for Disease Control considers the most important in causing foodborne illness—*Campylobacter jejuni*, *Listeria monocytogenes*, and *E. coli* O157:H7. *C. cayetanensis* first appeared in 1979 and is still not well understood. It is likely that scientists will discover new foodborne pathogens as laboratory techniques improve.

As living organisms, pathogens are constantly evolving. With better ability to trace outbreaks, scientists are discovering that some bacteria survive in environments previously thought safe. For example, *E. coli* O157:H7, originally called "hamburger disease" because of its presence in undercooked ground beef, has shown up in foods as diverse as salami, apple cider, raw milk, and lettuce. It also survives in lower pH conditions than originally thought, leading to the outbreaks in acidic foods such as salami and apple cider. It is now known that *Yersinia enterocolitica* and *L. monocytogenes* can survive and multiply at refrigeration temperatures.

Some foods long considered safe have recently been implicated in foodborne outbreaks. For years scientists believed the inside of an egg was sterile and that *Salmonella enteritidis* was not of concern. Now however, they know that chickens infected with *Salmonella* pass this infection along in their eggs, so that the bacteria can be found inside the raw egg, making it unsafe to eat raw or undercooked eggs. This was not known until 1989. Knowledge of this fact caused food safety experts to advise people to cook eggs thoroughly or to use liquid pasteurized eggs.

Bacteria have long been capable of evolving to thwart attempts to eliminate them. Some pathogens are now becoming resistant to common antimicrobial agents. It is thought that the resistance may be related to the subtherapeutic use of these antibiotics in animals. We are

seeing this same adaptability in foodborne bacteria. *Salmonella typhimurium* DT104 is widely distributed in wild and farm animals, especially in Europe, and is resistant to several common antibiotics. There has been a parallel increase with people getting sick from this type of drug-resistant *Salmonella*.

### History of Food Safety

Very little about foodborne illness or food safety is found in historical records. Scientists did not begin to understand bacteria, and their relationship to disease, until the late nineteenth century. People did recognize that food spoils, but the reasons for that and the potential for becoming ill from food were not known. The history of food safety is really the history of the numerous discoveries, inventions, and regulations that all led to the present knowledge.

Food preservation methods such as drying, smoking, freezing, marinating, salting, and pickling have their beginnings thousands of years ago. Whether these methods were employed solely to keep food for later use, to improve flavor, or for other reasons is not known; but for whatever reason they were developed, they also had the effect of keeping food safer. Even cooking can be viewed as an ancient method of making food safer. The Chinese Confucian Analects of 500 B.C.E. warned against consumption of sour rice, spoiled fish or flesh, food kept too long, or insufficiently cooked food. The Chinese disliked eating uncooked food, believing that anything boiled or cooked cannot be poisonous. It is possible that the practice of drinking tea originated because tea required using hot water, which would make it safer than using unheated contaminated water (Trager, 1995). Doubtless other cultures in antiquity, while oblivious to the causes or prevention of foodborne disease, experienced it and prescribed methods to avoid it.

Much of the present knowledge about pathogens and foodborne illness is built on a foundation of scientific discoveries spanning back over three centuries. Italians Francisco Redi and Lazzaro Spallanzani performed experiments that dispelled the theory of spontaneous generation of organisms. The discovery of bacteria in the late nineteenth century, the increased understanding of bacteria's role in disease, and the realization that there is a connection between human diseases and animal diseases led to the ideas that cleanliness is important and that unsanitary conditions can contribute to disease. A leader in this effort was Hungarian physician Ignaz Semmelweis, who in 1847 required hospital doctors to wash their hands before delivering babies. As a result, maternal death rates plummeted from 10 to 1.5 percent. His colleagues greeted his theory that doctors were carrying disease from person to person with ridicule. Instead they attributed maternal deaths to a phenomenon arising from the combustible nature of pregnant women. Lack of personal hygiene remains one of the main causes of foodborne illness 150 years later.

Louis Pasteur further elucidated the link between spoilage, disease, and microorganisms with his work on fermentation and pasteurization in the 1860s and 1870s. In 1872 German scientist Ferdinand Julius Cohn published a three-volume treatise on bacteria, essentially founding the science of bacteriology. But this new field of bacteriology needed bacteria on which to conduct experiments and study. It took Robert Koch in the 1880s to perfect the process of growing pure strains of bacteria in the laboratory. At first he used flat glass slides to grow the bacteria. His assistant, Julius Richard Petri, suggested using shallow glass dishes with covers, now commonly called Petri dishes. Koch also established strict criteria for showing that a specific microbe causes a specific disease. These are now known as Koch's Postulates. Using these criteria scientists can identify bacteria that cause a number of diseases, including foodborne diseases. In 1947 Joshua Lederberg and Edward Lawrie Tatum discovered that bacteria reproduce sexually, opening up a whole new field of bacterial genetics (Asimov, 1972).

Even though Antonie van Leeuwenhoek, a Dutch biologist and microscopist, had improved the microscope to the degree that small microscopic organisms could be seen as far back as 1673, the discovery of foodborne disease causing microorganisms developed slowly. Although James Paget and Richard Owen described the parasite *Trichinella spiralis* for the first time in 1835, and German pathologists Friedrich Albert von Zenker and Rudolph Virchow noted the clinical symptoms of trichinosis in 1860, the association between trichinosis and the parasite *Trichinella spiralis* was not realized until much later. The English scientist William Taylor showed in 1857 that milk can transmit typhoid fever. In 1885, United States Department of Agriculture (USDA) veterinarian Daniel Salmon described a microorganism that caused gastroenteritis with fever when ingested in contaminated food. The bacteria was eventually named *Salmonella* (Asimov, 1972). August Gärtner, a German scientist, was the first to isolate *Bacillus enteritidis* from a patient with food poisoning, in 1888. The case was the result of a cow with diarrhea slaughtered for meat; fifty-seven people who ate the meat became ill (Satin, 1999). Emilie Pierre-Mare van Ermengem, a Belgian bacteriologist, was the first to isolate the bacteria that causes botulism, *Clostridium botulinum*, in 1895. The case concerned an uncooked, salted ham served at a wake in Belgium. Twenty-three people became ill, and three died. In a perhaps overzealous use of the scientific method, M. A. Barber demonstrated that *Staphylococcus aureus* causes food poisoning. After each of three visits to a particular farm in the Philippines in 1914, he became ill. Suspecting cream from a cow with an udder infection, Barber took home two bottles of cream, let them sit out for five hours, drank some of the cream, and became ill two hours later with the same symptoms as on the farm. He isolated a bacterium from the milk, placed it in a germ-free container of milk, waited awhile, and then convinced two hapless volunteers to drink the milk

with him. Sure enough, they all became ill with the same symptoms (Asimov, 1972). In 1945 *Clostridium perfringens* was first recognized as a cause of foodborne illness. It was not until the years 1975 to 1985 that scientists first recognized some of today's major foodborne pathogens—*C. jejuni*, *Y. enterocolitica*, *E. coli* O157:H7, and *Vibrio cholerae*.

### Food Safety Regulations

The earliest food safety regulations in the United States were motivated not by a desire to provide safe food to consumers, but rather out of foreign trade concerns. In 1641 Massachusetts passed the Meat and Fish Inspection Law to assure foreign trading partners that the colony produced high-quality food products. Until the late nineteenth and early twentieth century state and local governments regulated food. Most food was grown and produced locally, so local laws were adequate to deal with problems. As the population changed from rural to urban, and people no longer had a personal connection with food producers, the food supply became more national in scope and distribution. This national scope necessitated national regulation.

The year 1906 was an important one for federal food safety regulation with the passage of both the Pure Food and Drug Act and the Federal Meat Inspection Act. The public was fed up with shocking disclosures of unsanitary conditions in meatpacking plants and the use of poisonous preservatives and dyes in foods. In *A Popular Treatise on the Extent and Character of Food Adulterations* consumers read that almost every food they purchased was adulterated or mislabeled. The Poison Squad, a group of USDA chemists formed in 1902 to study preservatives used in food products by eating the foods themselves, revealed that many of the chemicals used in food production were harmful to human health. Upton Sinclair's 1906 novel, *The Jungle*, highlighted the horrible working conditions of the nation's working class by describing in lurid detail the filthy conditions and adulteration of meat that was common in the Chicago meat industry. The public was more horrified at the thought of rats and other undesirables mixed in with their sausage than of the poor treatment of workers. Sinclair later wrote, "I aimed at the public's heart and by accident hit it in the stomach." Meat sales dropped by half within weeks after the book's publication.

The Federal Meat Inspection Act protected consumers by "assuring that meat and meat food products are wholesome, not adulterated, and properly marked, labeled, and packaged." The act established sanitary standards and mandated continuous inspection of cattle, sheep, goats, and equines before, during, and after slaughter. The 1906 Pure Food and Drug Act forbade the adulteration of foods, drinks, and drugs in interstate commerce. Foods were considered misbranded if they were labeled so as to deceive the public, if the contents in terms of weights and measures were either incorrect or not present on the package, or if the label contained

any false or misleading statement concerning the ingredients of a food.

Although it was a good start, the Pure Food and Drug Act had some very large flaws. Since it did not set standards as to what exactly should be in a particular food, it was almost impossible to prove adulteration of a food. For example, without knowing how much strawberry was supposed to be in strawberry jam, federal lawyers could not prove that a product with almost no strawberry in it was not strawberry jam. The act required the government to prove that offenders intended to deceive or poison consumers with their product. When brought to court defendants pleaded ignorance of the results of their actions. These deficiencies led to a renewed push for regulatory reform in the 1930s.

In 1933 Arthur Kallet and F. J. Schlink published the immensely popular book *100,000,000 Guinea Pigs: Dangers in Everyday Foods, Drugs and Cosmetics*. Written in true muckraking style, it stirred the public's ire at the condition of the food they were eating. The basic premise of the book was that the federal government was unable to protect consumers from bad food and drugs, both due to incompetence and to the lack of adequate laws.

As with passage of the 1906 act, public opinion played a strong role in sending the message to Congress that reform was needed. Since much of the media sided with the food manufacturing industry against reform, the Food and Drug Administration (FDA) took its message directly to the people, speaking at women's clubs, to civic organizations, and on the radio. The FDA collected hundreds of products (both food and drug) that had injured or cheated consumers, emphasizing that the 1906 act did not regulate these products enough to prevent such occurrences. The exhibits were photographed and converted into posters to illustrate the need for new laws. They were displayed at FDA talks and at a museum in FDA headquarters. The exhibit was christened the "Chamber of Horrors," leading to the publication of *The American Chamber of Horrors* by the FDA's Chief Educational Officer, Ruth deForest Lamb, in 1936. Ms. Lamb recounted some of the little-known, and sickeningly lurid, behind-the-scenes details of the food industry. In arguing the need for a new food and drug law, she noted that the 1906 laws were outdated due to new modes of living, new kinds of products, new methods of manufacturing and selling, new tricks of sophistication, and new scientific discoveries, all demanding a more modern method of control.

Finally, in 1938, Congress passed the Federal Food, Drug, and Cosmetic Act (FDCA). This act, with a number of adjustments and amendments, is still the major force regulating foods. It continued with many of the intentions of the 1906 act, but broadened the scope of federal regulation and plugged many of the loopholes. For the first time the law defined adulteration to include bacteria or chemicals that are potentially harmful; allowed

the FDA to inspect food manufacturing and processing facilities; required ingredients of nonstandard foods to be listed on labels; prohibited the sale of food prepared under unsanitary conditions; gave the FDA the authority to monitor animal drugs, feeds, and veterinary devices; and authorized mandatory standards for foods. Few laws have as great an impact on the life and health of Americans as does the Food, Drug, and Cosmetic Act. The overall function of the law was to prevent the distribution of harmful or deceptive food and drug products.

Seafood regulation came about on a voluntary basis with the Seafood Inspection Act of 1934. In the early 1930s, canned shrimp processors found that the FDA was seizing increasingly large amounts of their product because of decomposition. Poor fishing practices and poorly supervised packing operations contributed greatly to the spoilage of shrimp products. As the canners could not themselves influence fishermen and packers to improve their handling of the product, they requested that Congress enact an inspection law. Packers of any seafood product could request an inspector to examine the premises, equipment, methods, containers, and materials used. If the inspection was favorable, they could use that information on their label. The new seafood inspection program had an almost immediate favorable effect on the canned seafood industry. Product quality improved and the industry was able to regain consumer confidence in its product.

In August 1996, Congress signed into law the Food Quality Protection Act (FQPA), fundamentally changing the way the Environmental Protection Agency (EPA) regulates pesticides used in the production of food. The FQPA sets special provisions concerning pesticide ingestion for infants and children. Because little data exist on pesticide intake for children, an additional safety factor of up to tenfold, if necessary, is to be used. All existing tolerances are to be reviewed within ten years, and consideration of children's special sensitivity and exposure to pesticide chemicals must be taken into account when setting tolerance levels. The EPA is now required to periodically review pesticide registrations, with a goal of establishing a fifteen-year cycle, to ensure that all pesticides meet updated safety standards. Most importantly, the new law establishes a health-based safety standard for pesticide residues in all foods. It uses "a reasonable certainty that no harm" will result from all combined sources of exposure, including drinking water, as the general safety standard. This last facet of the FQPA is perhaps the most important because it eliminates the Delaney Clause of the Food, Drug, and Cosmetic Act, which prohibited the addition of any cancer-causing substance, no matter how small the amount, from being added to foods.

### **Hazard Analysis and Critical Control Points (HACCP)**

In 1996 USDA issued its Pathogen Reduction: Hazard Analysis and Critical Control Points (HACCP) System

rule. This rule requires that all 6,500 meat and poultry processing plants in the United States operate under a HACCP system. The FDA began its own HACCP regulations with a 1995 rule that mandated seafood processing facilities must have in place a HACCP plan by 1997. The 1999 FDA Food Code incorporates HACCP principles and in 2001 the FDA mandated that all producers of fruit and vegetable juices use HACCP principles by 2004.

Since the passage of the Meat Inspection Act in 1906, inspectors had visually examined and smelled meat to determine if it was safe or not. Such methods are not effective against the main threat to the safety of food today—bacteria so small that they cannot be seen or smelled. The failure of inspection methods in the United States came to the fore in 1993 when an outbreak of *E. coli* O157:H7 in hamburgers in the northwestern United States sickened over five hundred people and killed four. This provided the final push needed for the U.S. Department of Agriculture (USDA) to issue the Pathogen Reduction: Hazard Analysis and Critical Control Points (HACCP) System rule in 1996. Under HACCP regulations, the food processing industry assumes primary responsibility for the safety of the food it produces. The government's role is to verify that the industry is carrying out its responsibility, and to initiate appropriate regulatory action if necessary.

HACCP started from a National Aeronautics and Space Administration (NASA) food safety program in the 1960s. NASA needed to come as close as possible to 100 percent assurance that the foods astronauts consumed while on space missions would be free of bacterial or viral pathogens. NASA, the U.S. Army Natick Laboratories, and the Pillsbury Company began to develop these first space foods. While Pillsbury researchers struggled with problems such as how to keep food from crumbling in zero gravity, they also realized that traditional food quality control programs would not provide the degree of safety desired. To produce the safest food possible, they needed to have control over their production process, the raw materials, the environment, and their employees. To provide this level of control, in 1971 they introduced the HACCP system.

A typical HACCP system identifies critical points during food processing where contamination is likely to occur. Then, controls can be put in place to focus on these critical areas. Traditionally, industry and regulators depended on spot-checks of manufacturing conditions and random sampling of final products to ensure safe food. This approach, however, tends to be reactive, rather than preventive. HACCP is a preventive, systematic approach to food safety, rather than a reactive method. One key advantage of HACCP is that it focuses on identifying and preventing hazards that may contaminate food, thereby allowing control to be exerted in the manufacturing phase, rather than after food is produced. HACCP permits more efficient and effective government regulation,

primarily because record keeping allows investigators to see how well a firm is complying with food safety laws over a given extended period rather than only on a given day. HACCP has achieved international recognition as the most effective means of controlling foodborne disease. The National Academy of Sciences, the joint Food and Agriculture Organization/World Health Organization Codex Alimentarius Commission, and the U.S. National Advisory Committee on Microbiological Criteria for Foods (NACMCF) all endorse the use of HACCP.

HACCP involves seven principles:

1. Analyze potential hazards (biological, such as a microbe; chemical, such as a toxin; or physical, such as ground glass or metal fragments) associated with a food and determine measures to control those hazards.
2. Identify critical control points in the production of a food—from its raw state through processing and shipping to consumption—at which it is possible to control or eliminate the potential hazard. Examples are cooking, cooling, packaging, and metal detection.
3. Establish preventive measures with critical limits for each control point. For a cooked food, this might include setting the minimum cooking temperature and time required to ensure elimination of harmful microbes.
4. Establish procedures—such as how cooking time and temperature should be checked, and by whom—to monitor critical control points.
5. Establish corrective actions to be taken when monitoring shows that a critical limit has not been met—for example, reprocessing or disposing of food if the minimum cooking temperature is has not been attained.
6. Establish procedures to verify that the system is working properly—for example, testing time and temperature recording devices to make sure that a cooking device is working properly.
7. Establish effective record keeping to document that the HACCP system is working properly, by maintaining records of hazards, methods to control them, monitoring to ensure safety requirements are met, and actions taken to control potential problems.

To protect the public from foodborne illness, more and more of the U.S. food industry is operating under voluntary or mandatory HACCP controls. The Food and Drug Administration issued HACCP regulations requiring seafood processing facilities to have a HACCP plan in place by 1997. The 1999 FDA Food Code incorporated HACCP principles, and much of the retail food industry is moving toward implementation of HACCP requirements. In 2001, the FDA implemented HACCP regulations for fruit and vegetable juices after several high-profile foodborne illness outbreaks from the consumption of contaminated juice. The dairy industry is

also moving toward adopting a HACCP systems, as are other sectors of the food industry

### **Food Safety at the International Level**

Several international organizations interact to improve the safety of the world's food supply. The Food and Agricultural Organization (FAO) was founded as part of the United Nations in 1945 to raise levels of nutrition and standards of living, to improve agricultural productivity, and to better the condition of people in rural areas. Food safety is an important part of FAO's mission since foodborne disease is one of the most widespread threats to human health, as well as an important cause of reduced economic productivity. The World Health Organization (WHO), founded in 1948, has as its mission to set global standards of health and to aid governments in strengthening national health programs. WHO recognizes that protecting consumers from contaminants and preventing foodborne diseases are two of the most important strategies for overcoming malnutrition in the world. WHO's activity in food safety issues centers around development of national food safety policies and infrastructures, food legislation and enforcement, food safety education, promotion of food technologies, food safety in urban settings and in tourism, surveillance of foodborne diseases, and monitoring of chemical contaminants in food. FAO and WHO collaborate on many food safety issues as joint FAO/WHO committees and conferences.

One of the most important joint FAO/WHO commissions is the Codex Alimentarius Commission. This body has as its task the development of uniform food standards that can be used by governments throughout the world. This food code is known as the Codex Alimentarius. The Codex Alimentarius consists of food standards for commodities, codes of practice for hygiene and technology, pesticide evaluations and limits for pesticide residues, evaluations of food additives, guidelines for contaminants, and evaluations of veterinary drugs. Although the main goal of the Codex is to set uniform regulatory standards in the interests of international trade, it has also served to raise food safety standards in many countries. One hundred forty member nations accept its standards and follow its codes of practice.

**FOOD SECURITY.** Most people are familiar with the terms "national security" or "home security," but relatively few are familiar with the term "food security." These terms convey a sense of an absence of or lowered risk; a home is less likely to be burglarized, a nation's state secrets are less likely to fall into the hands of unfriendly nations. Food security has similar connotations in relation to food. According to the 1996 World Food Summit, food security exists "when every person has physical and economic access at all times to healthy and nutritious food in sufficient quantity to cover the needs of their daily ration and food preferences, in order to live a healthy and active life."

In its simplest form, food security means that all people have enough to eat at all times to be healthy and active, and do not have to fear that the situation will change in the future. As a concept it can be applied at many levels—global, national, household, and individual.

There are three fundamental pillars in achieving food security. The first is food availability. At the global level this is the key factor—sufficient food must be grown to ensure that everyone can be adequately fed. In the early 1970s several political missteps, combined with droughts, raised concerns about whether this could be attained. Indeed the crises of the early 1970s which resulted in high world grain prices led to an international conference in 1974 and the founding of the International Fund for Agricultural Development (IFAD), the World Food Council, and the FAO Committee on World Food Security. Today the world is food secure from the perspective of food availability, and global grain prices are less costly in real terms than at any time in recent decades.

## FAMINES

Famines, the worst manifestations of food insecurity, occur in specific areas when widespread and extreme hunger result in drastic weight loss and a rising death rate. They generally occur in rural areas and are the result of a complex interaction of factors such as drought, civil unrest, floods, and economic disruptions. Today, famines are rare and should be confined to the past. There is more than enough food in the world to feed everyone. Global information systems enable policymakers to predict when famine is likely, either as a result of crop failure due to drought or pest or because of civil unrest and war. Famine in today's world is testimony to policy failure, not the absence of food. Food insecurity, on the other hand, is a fact of life today for many people. Today, 815 million people go to bed at night not knowing whether they will have enough to eat tomorrow. Each year, more than 6 million children do not live to see their fifth birthday. They die silently of causes associated with hunger and malnutrition, absent the widespread media attention that famine attracts.

The next pillar of food security is access to food—economic and physical. This pillar is critical at the national and household levels. At the national level, if a country does not produce all the food it consumes then it must import food. A number of countries are too poor to purchase food on the international market and thus have a structural food deficit. International food aid must make up the shortfall. At local and household levels the market distribution system needs to be adequate to ensure that food is available at all marketplaces.

At the household level, sufficient levels of food must be grown, or purchased at the marketplace, or some combination of the two. Thus poverty plays the major role in food insecurity. Generally, if there is too little food it is the result of inadequate food demand driven by poverty rather than of market failure.

The third pillar of food security is food utilization, important at the household level and critical at the individual level, which brings together both the quality of the food and other complementary factors such as safe water that underpin good nutritional outcomes. This is the pillar that ensures the nutritional outcomes of every individual in the household are adequate. This is a very complex pillar. First, the household must be able to obtain, through production or purchase, the right types of food for all household members. Inadequate dietary diversity, which results in mineral and micronutrient deficiencies, increases the incidence of sickness, which sets up a vicious cycle of malnutrition. Second, unsafe water and poor sanitation increase the likelihood of frequent illness, which affects nutritional outcomes. Third, mothers need to have sufficient time to care for small children who require frequent feeding. In the developing world many poor mothers face excessive time burdens given the absence of electricity, or running water, or labor-saving food preparation devices. Many hours can be spent fetching firewood and water, growing food, processing it, and finally cooking it. Fourth, food must be available to all household members according to their needs. In some areas of the world, notably south Asia, girls and women in poor households often receive less food than they need even though the household has sufficient amounts. They are also less likely to receive health care when they become sick. In 1995 more than 6 million children died of causes associated with being underweight. Today the growth of one in three children five years old and younger is stunted, that is, they are too short for their age, a stark testimony to a life of too little food and too much sickness.

International concerns with regard to food security have shifted in the last three decades. In the 1960s and early 1970s, with rising world grain prices, fears arose that the world would run out of food in the future as its population grew ever larger. Major improvements in agricultural productivity, particularly the impact of the “Green Revolution” on wheat and rice, have removed that fear despite a population that increased from 1.6 bil-

lion in 1900 to 6.1 billion by 2000. Today the expectation is that new advances in agriculture, particularly in biotechnology, will increase agricultural productivity sufficiently to feed a world population expected to stabilize at about 9.3 billion. This expectation, together with abundant global grain supplies at record low prices, has removed the specter of food insecurity from the agenda of most policymakers.

Today, the focus of the international development community and many policymakers is on the AIDS crisis in Africa, which is finally attracting enormous attention and with it the promise of more economic assistance. AIDS kills about 6 million people a minute, a tragedy by any definition. Yet this tragedy pales in significance when compared to the 12 million people a day who die of causes related to malnutrition, the ultimate outcome of food insecurity. The 1996 World Food Summit called for the number of undernourished people in the world to be cut in half by 2015—a not insurmountable goal given current world food supplies and their predicted trend. Reducing hunger and food insecurity today is a matter of political will. However, past performance indicates the goal is unlikely to be met. Despite falling food prices during the 1990s, the number of undernourished fell by only 40 million, with the average rate of decline slowing to just 6 million per year by the end of the

decade. Achievement of the WFS target requires that at least 22 million people a year are removed from the ranks of the food insecure.

Recognition that food supplies are adequate but political will lacking has led to a new emphasis on food as a human right. The plan of action emanating from the 1996 WFS highlighted the need to implement Article 11 of the International Covenant on Economic, Social and Cultural Rights and called on countries, United Nations agencies, and intergovernmental agencies to better implement and realize the fundamental right of everyone to be free from hunger. In 2001 the international food security community has a double focus with a delicate balance—how to engage sufficient political will to secure food as a human right today, while maintaining a commitment to increasing agricultural productivity that will be required if we are to feed a more than 50 percent larger population by midcentury without further damaging the environment in the future.

**FOOD STAMPS.** The Food Stamp Program (FSP) is intended to help low-income individuals and families meet their basic nutritional needs. Although the first food stamps were issued to needy families in 1939, the FSP was not authorized as an official food-assistance program until 1964. In 1974, all states were required to offer food

stamps, and in 1977 participation increased when eligible persons no longer had to buy food stamps with cash. Participation in the FSP continued to increase through the mid-1990s, until the Personal Responsibility and Work Opportunity Reconciliation Act (PRWORA, also known as “welfare reform”) of 1996 reduced the number of people who were eligible.

In the early twenty-first century, the FSP remained the largest of the fifteen federal food-assistance programs, providing aid to an estimated 17.3 million individuals in 2001. An analysis of participants in 2000 showed that 51 percent were children (eighteen years or younger), 39 percent were nonelderly adults, and 10 percent were elderly adults. About 70 percent of participating adults were women. The majority (89 percent) of FSP households included a child, or elderly or disabled person. Of the households with children, 68 percent were headed by a single adult. Average gross monthly income per household was \$620, with 89 percent of households having gross monthly incomes below 100 percent, and 58 percent having gross monthly incomes below 75 percent, of the federal poverty guideline. In 2000, 40 percent of participants were white, 36 percent were non-Hispanic African Americans, 18 percent were Hispanic, and 6 percent were of another race or ethnicity.

The total cost of the FSP in 2001 was approximately \$17.8 billion, of which \$15.5 billion was distributed in the form of food stamps. These numbers are noticeably lower than in 1994, when expenditures peaked at \$24.5 billion and the number of participants also peaked, at 27.5 million (see Table 1). Trends in FSP participation and expenditures parallel trends in poverty and reduced unemployment. They also reflect changes in FSP policy and lack of information about such changes—the most likely reason why the participation rate among persons who remained eligible decreased from 74 percent in 1994 to 57 percent in 1999.

The FSP is administered at the federal level by the Food and Nutrition Service of the U.S. Department of Agriculture, but eligibility and distribution of benefits are administered by state and local agencies. In 2002, a household qualified for Food Stamps if its gross income was less than 130 percent of the federal poverty guideline (for example, \$1,585 per month for a three-person household as of 1 October 2001), if net income after certain deductions (such as for child care) was less than 100 percent of the poverty guideline (for example, \$1,220 per month for a three-person household as of the same date), and if countable assets (such as a bank account, but not a home or lot) were less than \$2,000 (or less than \$3,000 if the household had an elderly member). After the PRWORA took effect in 1997, legal permanent-resident aliens not employed in the United States for the past ten years could no longer receive FSP assistance, and most adults who were able-bodied, nonworking, and childless could receive only three months of aid in any thirty-six months. In addition, the maximum FSP benefit amounted to 100 percent of the

TABLE 1

**Food Stamp Program Participation and Costs**

Fiscal Year	Average Participation Thousands	Average Benefit Per Person Dollars	Total Benefits	All Other Costs Millions of Dollars	Total Costs
1969	2,87	86.63	228.8	21.7	250.5
1970	4,340	10.55	549.7	27.2	576.9
1975	17,064	21.40	4,385.5	233.2	4,618.7
1980	21,082	34.47	8,720.9	485.6	9,206.5
1985	19,899	44.99	10,743.6	959.6	11,703.2
1990	20,067	58.92	14,186.7	1,304.4	15,491.1
1995	26,619	71.26	22,764.1	1,855.5	24,619.6
2000	17,158	72.78	14,984.8	2,073.3	17,058.1
2001 (P)	17,316	74.77	15,536.1	2,253.9	17,790.0

Data as of 25 April 2002. Fiscal Year (FY) 2001 data are preliminary; all data are subject to revision. "Average Benefit per Person" represents average monthly benefit. "All Other Costs" includes the Federal share of state administrative expenses and employment and training programs. It also includes other Federal costs (such as printing and processing of stamps, antifraud funding, and program valuation). Puerto Rico initiated Food Stamp operations during FY 1975 and participated through June of FY 1982. A separate Nutrition Assistance Grant was begun in July 1982.

Thrifty Food Plan (TFP) allowance (reduced from the 103 percent issued in 1988). The TFP identifies types and quantities of foods for twelve age-gender groups that would meet the respective 1989 Recommended Dietary Allowances (RDAs), the 1995 Dietary Guidelines for Americans, and the U.S. Department of Agriculture's Food Guide Pyramid serving recommendations, according to data from the 1989–1991 Continuing Survey of Food Intake by Individuals (CSFII) and according to national average food prices. Eligibility for the FSP has changed constantly, however, as demonstrated by the decision in 1998 to restore Food Stamp benefits to children, elderly, and disabled individuals who were legal permanent residents in the United States. The U.S. Department of Agriculture maintains a toll-free telephone number to answer questions about current policies of the FSP.

In 2001, FSP participants received an average of \$75 per person monthly in the form of paper coupons in denominations of \$1, \$5, and \$10, or as electronic benefit transfers (EBTs). The computer-based EBT system employs a plastic card that functions like a bank debit card, allowing items to be purchased without the exchange of cash or coupons. The implementation of the EBT system was intended to make Food Stamp fraud (such as the exchange of cash for coupons at a lower value) more difficult. As of October 2001, thirty-seven states and Washington, D.C. issued all Food Stamp benefits in the form of EBTs. The PRWORA of 1996 mandates that all states use EBTs by October 2002.

Food Stamp coupons or EBTs can be used to buy foods such as breads and cereals, fruits and vegetables, meats, fish and poultry, and dairy products, and to buy

seeds and plants that produce food, from an estimated 155,000 authorized stores in the United States. But coupons or EBTs cannot be used to buy beer, wine, liquor, cigarettes or other forms of tobacco; nonfood items like pet foods, household supplies, or toiletries; foods that can be eaten in the store; or hot foods. Food Stamps also cannot be used to buy dietary supplements, including vitamins and minerals, a controversial policy that has undergone much scrutiny.

Evaluation of the impact of the FSP on the diets of participants is mixed. Using data from the 1996–1997 National Food Stamp Program Survey (NFSPS), average nutrient intakes of FSP participants exceeded the RDA, but a substantial number of households had folic acid and iron intakes below the respective RDAs. Data from the 1994 to 1996 CSFII and the Third National Health and Nutrition Examination Survey (NHANES III) show that FSP participants had higher intakes of most nutrients than other adults, but that median intakes of vitamin E, calcium, and zinc still fell below the respective RDAs. Within population subgroups, Food Stamps have been associated with improved nutrient intakes in children but not among the elderly. Interestingly, Food Stamp participants are more likely to be food-insecure, meaning their household does not have enough food to eat at all times. However, this counterintuitive finding is credible because people who are food-insecure are more likely than others to apply for and receive Food Stamps. The dietary quality and food security of Food Stamp participants after the implementation of the PRWORA of 1996 and subsequent changes in FSP policy are of keen interest.

**FOOD STUDIES.** Although accounts of food and eating habits date to the earliest written records, the designation of more scholarly investigations of food as food studies is a modern development. In the 1990s researchers began applying this term to descriptions and analyses relying upon every conceivable method for studying the historical, cultural, behavioral, biological, and socioeconomic determinants and consequences of food production and consumption. The idea that such investigations might collectively constitute a legitimate field of study in its own right derived from earlier explorations of food practices within traditional academic disciplines. In the 1960s, for example, the folklorist Don Yoder popularized the term "foodways" to describe the entire range of food habits, behaviors, customs, and cultural practices associated with food consumption.

In the 1990s Boston University established a master's program in gastronomy focused on the cultural and culinary aspects of food consumption. In 1996 the Department of Nutrition and Food Studies at New York University began admitting students to undergraduate, master's, and doctoral programs in food studies, thereby formalizing this emerging field as a state-accredited academic entity. The NYU programs emphasize the ways individuals, communities, and societies relate to food within a cultural and historical context. In this view, food studies is an umbrella term that includes foodways, gastronomy, and culinary history as well as historical, cultural, political, economic, and geographic examinations of food production and consumption. Any field defined so broadly immediately raises questions, in this case related to the scope, methods, and acceptance of food studies as a distinct academic entity.

#### An Inclusive, Interdisciplinary Field

Because the concept of food studies is new, scholars investigating food topics have not yet reached complete agreement on what it should and should not include. Anthropologists, folklorists, and sociologists always have examined the relationships of individuals and populations to their food. In the era of economic globalization, with its food inequities and scarcities, precarious and often tainted food supply, concerns about diet and health, and fears of genetically modified foods and food bioterrorism, food is recognized as a "lens" through which to view, explore, analyze, and interpret society in the present as well as in the past. The breadth of this approach means

that food studies can also include applied disciplines that deal with the fundamental properties of food—culinary arts, food science, and nutrition, for example—as well as food history and culinary history, agriculture and food production, and descriptive and economic analyses of food systems and the food industry.

By its very nature, food studies is interdisciplinary and must rely on methods, approaches, and themes derived from other disciplines. In this sense it is developing in much the same manner as other interdisciplinary fields, such as American studies, women's studies, and performance studies, that emerged a generation ago. Food studies may be unusual, however, in the breadth of the disciplines on which it draws. Economists, historians, psychologists, nutritionists, agronomists, geologists, geographers, archaeologists, environmental scientists, legal scholars, political scientists, and historians—culinary and otherwise—all bring distinct methods of research and analysis to bear on food themes.

### Multiple Methods and Approaches

Traditional academic disciplines are often defined by the distinct methods used by scholars in conducting research. Certain areas of inquiry, for example, use surveys, participant observations, or analyses of texts, historical documents, social interactions, and self-reports. Because food studies emerged from the humanities and social sciences, researchers typically rely on ethnography, case studies, and historical investigations. Throughout the twentieth century, for example, anthropologists debated whether culture is rooted in tangible and concrete artifacts—the implements and debris of hunting, gathering, and cooking—or in ideas and belief systems. They asked why people chose certain foods and used them in certain ways. They examined how religious beliefs, practices, and rituals influenced dietary practices, and they compared those influences to the effects of the environment or evolutionary biology. Claude Lévi-Strauss, for example, used a classic anthropological approach in his study of the symbolic use of food in culture, *The Raw and the Cooked* (1979). In contrast, the anthropologist Sidney Mintz produced a quintessential example of food studies research in his book *Sweetness and Power* (1985), in which he traced the ways a single food substance, in this case sugar, transformed modern history and culture. Anthropologists have further expanded the scope of their investigations to include the nutritional implications of dietary practices.

Scholars in other fields also examine food themes from the perspectives of their traditional disciplines. Food historians investigate the ways in which foods have influenced world events in the past and present. Culinary historians focus on recipes and cooking techniques, exploring when, where, and how specific foods or ingredients might have been grown, produced, prepared, and consumed in different periods. Food sociologists focus on issues of hunger, malnutrition, and inequities of the global food supply as well as on societal determinants of

diet-related conditions, such as obesity or heart disease. Psychologists often investigate how and why people make food choices or such matters as eating disorders, food phobias, and the psychological connections between eating and taste, pleasure, and disgust. Scholars trained in literature or languages examine how novels, poems, and essays are enriched with food imagery or the ways in which travel writing and memoirs use food themes to express ideas or points of view. Because food studies draws on many such disciplines, encyclopedias of food history or culture necessarily include examples of many different scholarly approaches to the study of food.

### The Food Studies “Movement”

As participants in an emerging field, food studies researchers are not constrained by the methods and approaches of any one discipline, and they enjoy the freedom to study what they like in whatever way seems most appropriate. Because food studies is inherently interdisciplinary, its scholars must define their own research agendas based on elements incorporated from traditional disciplines. Because this flexibility may be perceived as unfamiliar or lacking in rigor no matter how excellent the quality of the work, the academic study of food itself, as opposed to studying food within a traditional discipline, is established in only a few universities. The field appears to be expanding, however. In the United States, culinary schools are broadening their offerings to include courses in food history and culture, and universities in France, Mexico, and Australia have established degree programs that emphasize food. To scholars writing about food, such developments constitute the food studies “movement.” As further evidence for this movement, they cite the series of books on food and culture established by university presses, such as those of Columbia University, Northwestern University, and the University of California; the breadth and depth of the culinary history and food studies collections of the Schlesinger Library at Radcliffe College and the Fales Library at NYU; and the proliferation of encyclopedias on food history and culture, such as those cited in the bibliography.

In part, the growing acceptance and legitimacy of food studies as a discrete field reflects increasing recognition that innovative scholarship often crosses disciplinary boundaries. In the academic environment, the identification of food studies as a separate field may not matter much. The very existence of the food studies movement encourages students and faculty in traditional academic disciplines to conduct research on food themes and facilitates the publication of scholarly work related to the role of food in society, culture, and commerce.

**FOOD SUPPLY AND THE GLOBAL FOOD MARKET.** Worldwide, the food supply available to people depends on a variety of environmental, technical, and sociopolitical factors, the relative importance of which have varied considerably in time as well as geographically. Environmental factors have governed food production and availability throughout history, and this remains so for many societies. However, in a world where food is abundant as never before, food supply is extremely vulnerable to economic and political interests, as well as technical factors, such as transportation and communications.

### Food Supply through the Ages

Before the advent of agriculture and the domestication of animals (c. 10,000 B.C.E.), hunting, fishing, and gathering provided enough food for small groups of people such as bands of wanderers. Along with agriculture came a sedentary way of life, and self-sufficient agricultural settlements appeared in every region of the world. In this type of environment, food supply was direct and immediate. Careful management of produce ensured the survival of every household member until the next harvest. Except for times of warfare or environmental calamities, the balance between food demand and food supply remained fairly stable. Though hunting and gathering societies are almost extinct today, agricultural villages still endure in many parts of the world.

As some of these villages grew into towns, however, things began to change. Societies became more complex as certain groups of people ceased to be directly involved in the production of food. Food supply and distribution became dependent on an increasingly complex set of relations among groups of different professions and ranks. Surplus food (mainly grains) was traded with neighboring settlements. Concentrated in a few hands, food became a means to political power.

The growth of empires is associated with the emergence of a professional specialist, the merchant, who ven-

tured into new territories exchanging food and other goods across borders, often between far-off places. Food began to be regarded as a commodity subject to the rationale of profit, and it eventually became the responsibility of the state to ensure an adequate food supply for its citizens.

The Industrial Revolution of the late eighteenth century was also an agricultural revolution that dramatically changed the way food was to be produced, distributed, and used in most of the world. Farming, fishing, and other food-production activities became large-scale enterprises, organized according to the principles of maximum productivity and maximum profit. Capital-intensive agriculture produced surpluses of a magnitude never before possible. The modernization of transport and communications, and the emergence of food-processing and food-packaging industries, made it possible to extend food trade on a global scale. In urban centers, supermarkets can offer not only frozen and packaged food, but also fresh produce year-round from all over the world. For some this increased food supply has created a sense of plenty, albeit a localized and exclusive one.

### Food Supply as a Political Weapon

In the twentieth century, food supply came under the rules of a new political and economic order. Large food stocks have proved to be one of the main geopolitical assets of rich nations. Most affluent countries are or have been large exporters of food, and they control the global food market to their advantage. Food prices are set at the major stock exchange institutions in North America, Europe, and Japan. In competing for the hegemony of the global food market, the United States, the world's main food exporter, has been engaged in "food wars" with Japan and the European Union. International organizations, such as the recently formed WTO (World Trade Organization), have been created to defuse these conflicts, as well as to balance the "market distortions" that affect less powerful nations.

The global food market is dominated by the most affluent countries, which, on average, have controlled almost 70 percent of the total value of imports and over 62 percent of the total value of exports of all agricultural products in the world since 1961 (see Table 1). During the last quarter of the twentieth century, these countries have been reducing the value of their imports while expanding the value of their exports. Food imports by these countries typically concentrate on specialized agricultural items, such as tropical fruits and selected vegetables, as well as coffee, tobacco, sugar, and tea, none of which is a staple in its place of origin. In order to meet the domestic demand for staples, many of the exporting countries of such products have to import large quantities of basic staples in exchange. From 1961 to 2000, the countries of Africa and Latin America increased more than eight times their imports of cereals, those of Asia more than four times, and those of Oceania more than five times.

\*Addition of data for Belgium and Luxembourg

SOURCE: Food and Agriculture Organization of the United Nations (FAOSTAT, on-line <http://www.fao.org>) May 2002.

Since the end of World War II, the global supply of cereals, the basic staples for most of humanity, has largely depended on the production and export capacity of some fifteen countries. In 1999, major cereal exporters held close to one-half of global cereal stocks (Food and Agriculture Organization of the United Nations, 2002; hereafter FAO). In the year 2000, the four largest cereal exporters, the United States, France, Canada, and Australia, produced over 495 million metric tons of cereals (wheat, maize, rice, sorghum, oats, and others), which

amounted to 24 percent of the total world production, and exported 164.8 million metric tons of cereals, 61 percent of the total world exports of cereals for that year. However, in past decades this proportion had been much larger, reaching as much as 78 percent in 1980 (see Table 2).

In addition to trade, food transfers between main producers and main consumers include “food aid.” Between 1970 and 2000, more than 336 million metric tons of cereals were shipped as food aid to countries in need.

Over half of these shipments came from the United States alone. In 1990, the United States donated 7.2 million metric tons of cereals, 43.3 percent of which went to African countries, 21 percent to Latin American countries, and another 21 percent to countries in Asia. Despite its humanitarian character, food aid can also be used to the advantage of food donors through the conditions that may be attached to shipments and the adverse effects that these shipments may have on the domestic markets of the recipient countries (Mittal, 2002).

Food power has been used directly to pressure nations for a desired change of policy. In the second half of the twentieth century, food sanctions were applied against a handful of countries for a variety of purposes. For example, the United States embargoed a number of nations including Cuba, Iraq, Iran, Libya, and Sudan, impeding or severely restricting food trade between the United States and those countries.

### Food Supply in the Twenty-First Century

In the twenty-first century, the food supply is conditioned by the rules of the global food market and global geopolitics, which affect decisions concerning the production and distribution of food at the national and local levels. The effective demand (purchasing power) of high-income buyers has precedence over the real demand of the nutritional needs of populations. For most people on earth, access to food depends on access to money and, for some,

on access to charity, and the expansion of agribusiness to the countries of the so-called Third World has seriously affected these countries' self-sufficiency in food. Food trade and food markets have become subject to rules over which the majority of farmers have no control, and this has serious implications for the livelihoods of entire populations.

In the large urban centers of the world, the regular supply of fresh produce concentrates in the expensive supermarkets of wealthy neighborhoods, while a large proportion of the population can go without enough to eat. Lack of access to food leads to undernourishment, a problem that affects more than 800 million people in the world, including many living in the rich, food-exporting countries.

Food supply has become subject to a complex set of interests that governments are finding increasingly more difficult to mediate. Cereal stocks at the global level seem to have begun a diminishing trend due to an overall decline in production and an overall increase in utilization. Estimates for the year 2000 indicated an expected 4 million tons, down from the opening levels (FAO, 2000).

Though the per capita supply of cereals has been growing steadily since 1961 in most regions of the world, food shortages afflict a large number of countries. In 2002, the FAO reported that a state of emergency existed in the food-supply systems of as many as thirty-four coun-

tries on four continents, including Europe (FAO/GIEWS, 2000). One of the factors that adversely affects real food supply per capita in many countries is the utilization of cereals as animal feed, which in 1999 amounted to 35.1 percent of total world cereal stocks (Faostat, World Food Balance Sheet, May 2002). Unless local small-scale production for self-consumption is protected and encouraged, continuous and adequate access to food cannot be guaranteed for the rural populations of the world. With rural-urban migration on the rise almost everywhere, the majority of populations in the world will soon be concentrated in cities, contributing to the expansion of already impoverished slums.

A series of fundamental changes in global trade and the international financial system is in order if food security for all is ever to be attained. In this regard, the efforts of civil organizations fighting for fair trade and a more egalitarian world society are crucial.

**FOOD SUPPLY, FOOD SHORTAGES.** A nation's food supply is determined by composition and selection. The components of a food supply are limited by a number of factors, primarily climate and geography. The U.S. food supply is noticeably different from that of other nations as the twenty-first century begins. Americans are more likely to recognize food products than the specific ingredients in the seemingly endless array of products on supermarket shelves (some supermarkets stock over forty thousand different items). Fast-food outlets—a McDonald's, Taco Bell, or a Subway sandwich shop—are more recognizable than a steer, hog, chicken, or a bushel of wheat. Most such foods are slaughtered, processed, manufactured, and packaged; few are sold in bulk, as was common before World War II. Nearly all foods are shipped from distant places on pallets or in large containers, transported to huge warehouse storage facilities or to freezers close to cities, and trucked from there to be unpacked and displayed on supermarket shelves or served in fast-food outlets.

The United States enjoys a temperate climate especially hospitable to agriculture that supports the production of a wide variety of grains, fruits, and vegetables as well as milk, meat, poultry, and fish. Within the U.S. landmass, soil conditions and characteristics ensure an abundance of available farm acreage, which, in turn, assures a profuse supply of food—so much so, in fact, that the U.S. Congress authorizes programs that pay landowners to keep portions of their farmland lying fallow. Purchasing, storing, and maintaining food surpluses cost taxpayers more than paying farmers not to produce, making payments to idle farm acreage the cheaper alternative. Income also is a significant element in the composition of the food supply.

#### Composition of the U.S. Food Supply

Americans are among the wealthiest populations of the world, and their wealth enables most U.S. citizens to purchase from abroad any food not available from U.S. agriculture or fisheries. The United States is a magnet for the world's food supply, drawing an endless trade caravan of meats, pastas, spices and herbs, sauces, cheeses and other dairy products, wines and spirits, cakes and crackers, and fish as well as exotic and conventional fruits and vegetables, mostly fresh. While income is a means of expanding the selection of foods available in an indigenous food supply, income more often is a limiting factor in the

availability of food in a population or in subgroups within a population.

Low-income families and individuals in the United States, for example, have a more limited food supply than do those with middle or higher incomes, although public policies today ease income barriers to a more adequate food supply by supplementing the purchasing power of low-income families and individuals. Still, even with the assistance provided by food stamps and other government programs, including school meals for children, low-income households can afford less for food than higher-income families, some \$1,000 less annually per person, and, as a result, consume food measurably lower in nutritional value.

Populations in poor countries (euphemistically called “less developed countries” [LDCs]), in contrast, are limited by income to the food supply readily available where they live. Trade in either conventional or exotic foods is not an option, since many of the world’s poor live outside a conventional marketing system. As a result, most citizens of LDCs grow or raise most of their food themselves, although imports are becoming increasingly important. In central Africa, for example, the food supply consists of locally produced staple foods such as maize, cassava, sweet potatoes, banana, millet, sorghum, and yams. Traditional vegetables, including the leaves of cassava and sweet potatoes, provide the vitamins and minerals otherwise largely lacking in these staple foods.

### **Food Supply: Sources**

Cereals provide 69 percent of dry matter and 55 percent of the protein in the world’s food supply by weight. Legumes—for example, beans—provide another 6 percent of dry matter and 13 percent of protein (Allard, 1999). Vegetables, fruit, meat and poultry, eggs, fish, nuts, sugar, and other sweeteners, in that descending order, provide the rest. People living in the United States and the countries in the European Union, as well as Canada, Japan, Australia, and New Zealand, consume a food supply with larger proportions of meat and poultry, dairy products, fruits and vegetables, fish, nuts, sugar, and oils and fat, a diet that delivers a substantially larger caloric load than that typically available in poor countries.

As personal incomes rise, the diet of individuals and nations shifts from basic food sources to those that provide a higher level of energy, or calories—animal products, more highly processed prepared foods, and oils and fat. Grains drop out of the human diet to become animal fodder as incomes rise, especially maize, oats, millet, and sorghum, which are then categorized as feed grains. Replacing grass and hay (traditional animal fodder), feed grains are fed to cattle, hogs, and chickens instead, reentering the food supply as beef, pork, poultry, milk, and other dairy products. Fish farming, or aquaculture, has emerged as a commercial source of freshwater fish and seafood in the last decade, and as a user of feed grain in rations fed to fish raised in underwater pens. Wheat is

the major food grain in the United States, although rice consumption is increasing with the rising proportion of Americans of Asian and Latin American descent, for whom rice is the major food grain.

The food supply varies by nation and by geographic region, reflecting religious beliefs as well as cultural practices. Devout Muslims and Jews do not eat pork. Koreans, Chinese, Vietnamese, and other citizens of Southeast Asian nations consider both dogs and cats enjoyable sources of animal protein, and horsemeat, a staple in pet food in the United States, is a delicacy eagerly consumed by the French and other Europeans.

During the 1990s, the American people increased spending on food consumed outside the home by nearly 25 percent, a whopping increase compared to the 4 percent growth in consumption of food prepared and eaten at home during the same period.

By the end of the twentieth century, the U.S. was unable to visualize the source of its food supply from an agricultural perspective, that is, in terms of basic food groups, because a majority no longer live on farms. Instead, food had become an endless array of food products typically found on supermarket shelves, especially those that stock over forty thousand individual items. Most such foods are processed and packaged, and few are sold in bulk as was common sixty years ago. Nearly all were shipped from distant places, packaged in large containers, transported to huge warehouse storage facilities close to cities and metropolises, and trucked from there to be unpacked and displayed on supermarket shelves.

Transporting the food supply long distances requires that foods arrive in a “safe” condition, meaning that they will cause no harm when eaten. Processing and packaging are traditional methods essential to safely preserving food ingredients, either by drying fresh fruits and vegetables, fish, meat, and poultry, by freezing them, or by cooking and canning them before they are transported and distributed. Food processors and manufacturers strive to convince the public of the differences between brands through advertising and promotion, but the only differences are frequently superficial marketing “hooks” introduced to change consumers’ perceptions of products in order to capture a larger share of their food dollars. Price competition keeps profit margins low. Basic ingredients do not change, but that fact can be hidden. For example, any breakfast cereal can be made to appear different and more appealing by producing it in different shapes or adding sugar, dried fruit, essential vitamins and minerals, or new flavoring or colors. Newly designed packaging, announced by a new advertising campaign, will successfully persuade consumers that the product itself is new and different.

A successful promotion is intended to achieve better differentiation of individual products, a product virtue that is more important than nutritional value. Processors do not ignore nutrition, however, especially if it has the

virtue of enhancing product differentiation. Differentiation of a product is an essential marketing function that enables a food company to charge U.S. consumers more for, or to sell more of, a basic food grain than might otherwise be possible. The availability of forty different packages of a breakfast food containing corn cereal in the breakfast food section of the supermarket is not intended to provide variety for consumers. The goal is to divide the market into increasingly smaller segments within which more can be charged per ounce than can be extracted from consumers for simple cornflakes. The same segmentation game can be played in every category of processed food. Differentiation ensures that food companies do not compete on the basis of price, traditionally the distinguishing feature of an openly competitive, free market in capitalist systems. New food products quickly come and go, but the basic ingredients—flour, fat, sugar, flavoring, coloring, and preservatives—remain unchanged. An estimated twelve thousand new food products are introduced annually, and fewer than a hundred will remain on supermarket shelves after five years.

Food processors and supermarkets, squeezed by restaurants and fast-food companies into a smaller portion of the commercial food market, have defended their share of the food supply by developing products that contain the main entree of a meal or a full meal packaged in dried or frozen form. Breakfast cereals come in small packages containing a single portion. Different recipes are devised for wheat flour, fat, sugar, jams and jellies, and artificial flavoring in partially baked pastries that can be heated in the kitchen toaster as a breakfast food or as a snack, for example. Full meals are packaged frozen, to be heated in a microwave and served as a quick lunch or dinner.

As a food category, the entree items and full meal products can be differentiated from other food products, enabling food processors to charge a higher price for a product than its often meager ingredients would bring if sold individually. Within the packaged meal category, product differentiation tactics often promote convenience as well as health benefits, both strong personal objectives, especially among individuals in the upper-middle and higher income brackets, the primary targets of advertising and promotion campaigns. Supermarkets over the past decade have given more floor space to and hired more employees for deli counters that offer convenience foods as well as whole meals, or home-meal replacements.

Needless to say, advertising, promotion, product development, and packaging design are not free services. They are the cost of marketing the food supply in a postindustrial society and a service economy. While the proportion of the food dollar spent to eat out grew from 44 percent in 1990 to 47.5 percent by the end of the twentieth century, consumer spending for food increased by 37 percent, with marketing costs responsible for almost all of the increase. Marketing costs in the decade rose 45 percent, compared to a rise of 13 percent in the

Mother with malnourished child in famine-stricken Somalia.

farm value of food purchases. Marketing consumed 80 percent of the trillion-dollar cost of the food supply system in the United States, leaving the actual value of the food supply at \$200 billion, or 20 percent of the operational cost of the food system as the twenty-first century began. As some corn growers mournfully point out, the cost of the package containing cornflakes is more than the farmer is paid for the ingredients.

These shifts in how money is spent for food reflect seismic changes in the social tectonics of the U.S. economy at the end of the twentieth century. Among citizens of developed countries globally, Americans alone were working more hours each week as the century ended than when it began. Employment during the 1990s rose faster than in any decade since the end of World War II. The structure of the nation's workforce changed as well. The number of two-income households rose as more women entered the workforce, and wages grew faster, even as inflation declined.

The consequences of more real income and less leisure time drove changes in the food supply system. Consumers purchased more food overall, but more higher-cost processed and packaged in-home foods. The practice of spending to eat out at restaurants grew rapidly, especially at fast-food outlets. As the twenty-first century began, the money spent on fast food consumed nearly

Due to wartime shortages, the National Live Stock and Meat Board in Chicago issued this 1944 booklet on tips for making the most of meat purchases during the national emergency. This included a pledge of the American homemaker: "I want to do my bit and more, to help America win the war." ROUGHWOOD COLLECTION.

one of every four dollars spent to eat out. Only a decade earlier, in comparison, one dollar in ten was spent on restaurant meals. Wages and employment in the food supply system rose, all in response to the search for convenience.

Consumers were working more, earning more, and willing to pay more for convenience and for appliances like the microwave, which made convenience foods more convenient. By the end of the twentieth century, only one in three U.S. consumers said their food budget was a primary consideration in food purchases, while the other two said service and convenience topped their list. Oddly, as convenience became the hallmark of the U.S. food system in the twenty-first century, more space and attention was being given to kitchens in new home designs, especially as the size and amenities in homes increased. In addition, kitchen utensils with as much decorative appeal as utility were being featured in up-

scale department stores and shops catering to consumers aspiring to culinary sophistication.

The prosperity at the end of the twentieth century, combined with the largely benign condition of inflation, led to an effective overall reduction in the portion of disposable income spent on food in the United States. At the close of the 1990s, U.S. households were spending 10.4 percent of disposable personal income on food, down from 11.4 percent in 1990. Household spending in 1999 was greater in four expenditure categories—medical care, housing and home expenses, transportation, and services—than it was in the category of food, for one simple reason: with each additional dollar of income, the share of family income that must be spent on food is less than the share from the previous dollar. As real income rises, more family income is available for other needs. Wealthier families allocated far less by half than 10 percent of disposable income to food, while families at the lower end of the low-income category were spending up to 40 percent of their disposable income on food.

### The Immutable Economics of Food

Regardless of the marketing ingenuity of food processors and supermarkets, or the culinary talent of restaurant chefs, the food system cannot escape the reality of the inflexible economics of food. The typical stomach can hold only a finite amount of food. After a certain point, the stomach becomes inelastic; the same is true of the economics of food. To put a finer point on the observation, an individual who has not eaten for twenty-four hours may be willing to pay twice the asking price for a tempting meal, but, once the meal has been eaten, few individuals will pay a dime more to consume the same meal immediately.

Food also obeys the law of inelasticity. The need for food is constant, and people who are starving will pay almost anything, do anything, to get enough to eat. Survival depends on a minimum intake of food, averaging between 1,800 to 2,400 calories per person daily, that will also ensure adequate levels, or stores, of essential oils, fats, vitamins, and minerals. Humans can, and do, survive on less, but at a physical and physiological price measured in stunted growth and susceptibility to chronic and infectious diseases. When food is scarce, food prices will increase; the more scarce food becomes, the more rapid the escalation in food prices.

When food is plentiful, in contrast, people will not pay more to obtain greater amounts of food than they need. Farmers who harvest more food than can be easily sold will be paid a substantially lower price for all the wheat, maize, rice, or hogs and cattle they sell in the market than they would receive without the excess production. When each farmer produces only slightly more one year than the last, the combined surplus can be so large as to devastate the income of all farmers, a condition that plagued U.S. agriculture for much of the twentieth century and now looms as a global condition. Farmers can-

not withhold their individual surpluses since the amount is too small to make a difference, but each farmer suffers measurably when the overall surplus is so large that commodity prices fall and profits are destroyed. No individual, cooperative, or company has the resources to acquire and store the excess food.

Farmers, food processors, and consumers each cope differently with the inflexible fact of inelastic stomachs, all with varying degrees of government intervention. With a food supply in which the value of food accounts for only 20 percent of the cost of the system, food processors have the comparative advantage of size and few competitors. Consolidation among competitors occurred rapidly at all levels in the U.S. food supply system in the 1990s, thanks to the benign attitude of the federal government toward anticompetitive behavior, creating a marketplace with enormous advantages for the survivors. The massive size of food processors—four companies essentially control processing of beef and pork, three companies dominate the poultry industry, and even these seven firms are exploring further consolidation—allows processors to largely control what they will pay to producers.

Although commodity prices in the United States are low by all historic standards, the cost of food is not as significant a factor for company management as stability of supply and the ability to either stabilize (fix) the cost or negotiate the price of ingredients. Processors with few competitors need to fix the cost of ingredients over the life of the marketing plan for a food product. Those costs will be only one factor to consider in setting the level of product prices in the development of marketing strategies that will produce a profit. With price competition virtually eliminated for grocery food items, the price obtained through product differentiation is the dominant management concern.

From the consumer's perspective, food costs are actually declining as a portion of rising household income, and food price inflation is largely absent. Both conditions are substantially influenced by government fiscal and monetary policy. As long as these conditions prevail, consumers are less likely to be upset about the growing market power of food processors than they would be if food price inflation were escalating as much as it did in the 1970s. As odd as it sounds, inflation is not a food supply issue today because of the convenience factor. Food processors and supermarkets would inflate food prices if they could, but restaurant and fast-food outlets would take a bigger share of food spending if they did. As long as consumers choose to eat out more, the food industry is stymied by the competition over market share from restaurants and fast-food outlets. Processors and supermarkets have yet to develop an effective counterstrategy to the competition of convenience and are unable to raise prices as much as they would like. With the consumer food dollar almost evenly split between eating out and eating at home, the food processor is being forced to get

by with a smaller piece of the pie, so to speak. Consolidation in the processing industry is an inevitable response, dividing the consumer dollar among fewer participants.

An additional factor limiting the ability of the supermarket industry to raise food prices is a recent invasion of competitors, especially from "big box" discount retailers. Both Wal-Mart and Target are rapidly adding grocery merchandising sections to their existing stores and building new stores that emphasize groceries and food. As a result, supermarkets are being pressured not only by restaurants and fast-food outlets, but also by competition from discount stores. Supermarkets are taking the pragmatic approach, "if you can't beat them, join them," by marketing whole meals prepared in the store. While seven of every ten take-out meals sold in 2001 came from fast-food outlets, supermarkets accounted for almost two of ten, leaving the remaining one percent of the take-out market to restaurants. As long as consumers have the disposition and the disposable income to eat at restaurants or fast-food outlets, they also have the most effective strategy for playing suppliers in the food system against another.

Farmers cope with the changing trends in the food supply system with the one tool still available to them, aid from the federal government. In 1995, Congress enacted legislation to end government intervention in agriculture by phasing out income-support programs. However, when farm incomes fell in 1998 and in the following years, Congress quickly authorized emergency income payments and added another \$30 billion over the next three years to already generous subsidies and government payments. In 2002, the first new farm legislation of the twenty-first century was adopted. The most generous in the sixty-year history of farm programs, the new legislation provided income support payments to farmers of over \$19 billion a year for the following ten years. The scale of the subsidies allocated by Congress is unparalleled. Legislators in Washington have guaranteed that American farmers will receive nearly \$200 billion in income payments over ten years, the equivalent of the farm share of annual consumer spending for food. Over 90 percent of farm output in the United States was harvested by some 200,000 farm operators who would receive most of the \$19 billion in annual farm income payments. Globally, agriculture production is rising, a condition that experts predicted would drive down farm commodity prices further. If this pattern develops during the twenty-first century, even greater expenditures for farm support could be made by the federal government than had been projected under the existing farm legislation.

### **Immutable Law of Nutrition**

If the food supply is governed by the economics of inelastic stomachs, it is also bound to the immutable law of nutritional consequences. People consume food because

## MALNUTRITION

Malnutrition affects about 600 to 800 million people in the world, most of whom live in Africa and Asia, where food shortages occur more frequently and the food supply is tenuous and unpredictable. In Africa, the major cause is unstable governments combined with uncertain weather, a lethal social combination that undermines efforts to develop a more reliably productive agriculture capable of increasing domestic food production. Food assistance, mainly through the World Food Program, which distributes surplus food from developed countries, has been established worldwide to fill the calorie gap. However, food assistance treats the symptom, not the problem, and aggravates the search for long-term solutions by disrupting the agricultural economy when it is most vulnerable by displacing domestic markets.

of an instinct for survival, but life can be put in harm's way either by too little food or by eating too much food. People die of both starvation and gluttony. Nations are similarly at risk. If citizens, threatened by food shortages or famine, confront a food supply insufficient to fill shrunken stomachs, anarchy may ensue. A nation faces a no less compelling array of social, economic, and political problems when it confronts a food supply that is grossly greater than is needed. Surpluses can destroy the farming economy. If the nation dumps its surpluses on its neighbors, professing humanitarian impulses, the policy will destroy its neighbors' farming systems. If national leaders exhort people to eat their way out of the problem, or even if the surpluses are transformed into meat, poultry, and other forms of animal protein, then people will become overweight. In addition to surpluses, health costs will increase as well, and the national budget for health services will rise because obesity is a precursor to chronic diseases and overweight individuals are at risk of early death.

The U.S. public has come to accept that malnutrition is the consequence of too little food for too long a time. But malnutrition has two faces. It is a Janus-like condition of nutritional extremes, of either undernourishment or overnourishment, both of which may occur at the same time in a single population. In the United States and other developed countries, classic malnutrition, or undernourishment, most often occurs in predictable groups: women, children, the elderly, and the poor. The cause may vary, but malnutrition almost always accompanies poverty, which occurs more frequently

among these groups. Women are paid less than men for equal work, while four of every ten children live in poverty in the United States, where fewer than two of every ten families are poor. The proportion of the elderly who are poor continues to be greater than should be the case.

Malnutrition of the poor is not evident since undernourishment has few immediate, unique characteristics, although the condition will be visible eventually in the rising levels of infectious diseases, diarrhea, and tuberculosis. The overt signs of starvation, such as stunting, failure to thrive, kwashiorkor (extreme protein malnutrition, especially in children), or marasmus (chronic malnutrition, especially in children), are generally indicative of severe, widespread hunger throughout a population in which malnutrition already is extensive. Undernourishment in the United States, or in other highly developed nations, is not caused by food shortages but, instead, by barriers, almost always poverty, that block access to the food supply. There was no shortage of food in the world at the beginning of the twenty-first century, nor is there in the foreseeable future. Since the 1960s, the United States has established a series of federal nutrition programs to increase access to the food supply for groups of citizens at risk of hunger, including low-income families, children away from home, mothers and their infant children, and the elderly. The Food Stamp Program is intended to assist families and individuals, especially during rising unemployment and in seasonal periods when work is not available. The program also reaches families troubled by chronic unemployment and families in which the parents hold down two or more jobs but still earn only a poverty-level income. At peak unemployment in the early 1990s, nearly 25 million Americans were participating in the Food Stamp Program.

School meals, which include breakfast and lunch, are subsidized and served each day to more than 50 million schoolchildren, and schools receive additional subsidies to provide meals at nominal or no cost to over half of these children. Some 7 million mothers receive monthly certificates through the WIC (Women, Infants, and Children's) program to purchase infant formula and additional foods that provide nutrients needed especially by pregnant women and lactating mothers. The WIC Program also offers nutritional counseling and health information on pregnancy to expectant mothers. Over 2 million older Americans daily receive hot meals at nominal prices delivered to their homes or served in community centers through subsidies provided by the Older American Nutrition Program to community organizations. During the economic slowdown in 1991 and 1992, the federal government was spending over \$40 billion a year on nutrition programs, including \$27 billion on food stamps alone.

The unique characteristics of the U.S. food supply compared to other nations occur most notably in public policies. While the United States and the European

Union both subsidize their farm economies generously, other countries possess neither the wealth nor the political commitment to match this. At the beginning of the twenty-first century, the United States was projected to spend \$200 billion over the next decade in farm income payments, and an estimated \$350 to \$400 billion for food assistance. No other nation allocates as much overall or as a percentage of its gross national product to ensure access to food for the poor as does the United States. The U.S. government has taken a benign view of economic concentration in the food system, permitting the accumulation of economic power among a few corporations in every sector of the industry, ranging from livestock slaughter to poultry processing, farm equipment and chemicals, as well as food manufacturing and retailing. The European Union, in comparison, is more vigilant regarding competition as an economic force in a free enterprise system.

**FOOD TRADE ASSOCIATIONS.** Since the time of the first Crusade (1095–1099), early food trade companies shipped raw specialty commodities (primarily spices) from exotic lands, first from Egypt and Syria, and later from China, India, and Indonesia, to market ports in the colonial world. The Italian trade families of Venice and Genoa were particularly active, most notably the Polo family, which brought goods from China between 1260 and 1294. Perhaps the most important of these shipments were seed stuffs, which were conveyed great distances, then planted on domestic soils and genetically groomed to flourish in their new habitats, to eventually become some of the staple commodity crops—such as maize and wheat—of human history. Bartering goods in both directions, the early trading companies contributed to the wealth of their risk-taking owners and sponsors who paid for their explorations.

The successful trade of even nonessentials developed dependencies on imported goods; tea and coffee, for instance, became so prized that their trade was eventually manipulated for political purposes. Frequently subsidized by royalty, food trade companies easily became players in the political arena. The East India Tea Company, which still exists today, was the beneficiary of tea taxes that Great

Britain placed on its colonies in the early 1770s. When the practical Americans started drinking Dutch teas instead, the British placed tariffs on the Dutch teas, favoring their own trade association products at lower prices. That move was the impetus for the famed Boston Tea Party of 1773. After that, coffee rose quickly into American favor, having been introduced in 1600 to the West by Italian traders. So popular was the brew in the early 1960s that the coffee-producing and -consuming nations agreed to use export quotas to provide reasonable market prices and stabilize supplies. When that agreement was not renewed in 1989, the producers formed the Association of Coffee Producing Nations and developed the Coffee Retention Plan to balance supply and demand. Food trade associations had come of age and became a driving force in the global political arena.

Contemporary food trade associations may represent a commodity grower group, such as the National Cattlemen's Beef Association and National Corn Growers' Association in the United States; the Asociación de Exportadores de Chile (Association of Chilean Exporters, or ASOEX, fruit exporters); or the Association of British Salted Fish Curers and Exporters, and the Pea Pickers and Pea Packers, in the United Kingdom. Or they can represent a group of commodities and products that share a trading platform or set of technologies, such as the Grocery Manufacturers Association (GMA), American Frozen Food Institute, Biotechnology Industry Organization, and the National Food Processors Association (NFPA) in the United States; or the Cámara Nacional de Agricultura y Industria (National Chamber of Commerce for Agriculture and Industry) in Costa Rica.

These associations no longer physically trade food goods, but deal with a variety of issues that cannot be handled at the level of the food producers or processors individually, including coordination and collaboration in the marketplace on food safety, workers' rights, and agricultural health; public communication and education; distribution, pricing and marketing strategies; technical services; crisis management; and legal representation and lobbying in the international trade policy arena. Members (producers or processors), not owners or sponsors, reap the benefits of their efforts. Nowhere is this more apparent than in high-visibility marketing campaigns that have emerged for small-commodity products like raisins ("I heard it on the grapevine") and milk ("Got milk?").

Trade associations can be vitally important in legally defending an industry when it is involved in a trade dispute, for instance when it is charged with "dumping," as in the case of Chilean salmon defended in *Asociación de Productores de Salmon y Trucha AG (Association of Salmon and Trout Producers) v. the United States International Trade Commission* (2 July 1999), where tariff penalties were greatly minimized. Mexico's Asociación Agrícola Local de Productores de Uva de Mesa (AALPUM) and Chile's ASOEX successfully cleared their table grape growers of dumping complaints by the Desert Grape Growers

League of California in the spring of 2001. Court and lobbying fees in international trade disputes can mount into the millions, far beyond the capacity of individual producers in developing countries where government support for the industry is nonexistent.

Trade associations can wield enough power to countermand multilateral international treaties. The World Trade Organization was established 1 January 1995 out of the General Agreement on Tariffs and Trade (GATT) of the Uruguay Round to adjudicate trade disputes according to a scientific risk-based assessment. Now, many food trade associations, like the science-based NFPA and the GMA, participate actively in that process, supplying regulatory and scientific experts to the WTO Codex Alimentarius Committees to prevent the formation of future technical barriers to trade.

**FOOD WASTE.** Food waste is the discarding of potentially usable food. Both edible and inedible foods may be considered garbage and therefore wasted. Edible foods are considered inedible when their quality deteriorates until they become unhealthy or noxious. Food deterioration occurs from microbial contamination or from rotting as a consequence of overproduction, storage problems, or improper preparation. Food waste also occurs through food use that returns little nutritional value, like overprocessing and overconsumption.

Edible foods are also wasted when cultural or individual preferences deem food undesirable. For example, some people dislike bread crusts, so they remove them and discard them. Societies with abundant food supplies often consider reusing leftover foods as inconvenient, while less food-rich societies regard food reuse as imperative. Specific parts of animals and plants considered edible in some cultures are considered inedible in others. Animal parts viewed as waste may include bones or shells, skins or scales, fat, blood, intestines, brains, eyes, and

stomachs. Plant parts viewed as waste may include cores, seeds, stems, outer leaves, shells, rinds, husks, or peels.

#### Cultural Variations in Food Waste

Food systems in different cultures vary in the proportion of food waste that is discarded. Cultural variations exist in what is considered garbage, and understanding cultural food rules is crucial in examining food waste. For example, intestines and other internal organs are considered delicacies in China but are discarded as offal in many Western countries. Animal fats are consumed or used as fuel in societies like the Inuit, but in postindustrial nations fats are often trimmed and discarded to reduce caloric intake. Blood is an ingredient in dishes like black pudding in Britain but is discarded in many other societies.

Cultural differences in beliefs about what is edible versus inedible exist more often for animal foods than for plant foods. This may be because animals are similar to humans, so that edibility involves more symbolic meanings. Also, plant food wastes often constitute parts indigestible by humans that therefore have no nutritional value, such as vegetable rinds.

Moral values in most cultures admonish food waste. However, food protests and food riots may intentionally waste food to make ideological and ethical points. Many groups are proud of their efficient use of all parts of a slaughtered animal, such as Cajun claims to use “everything except the squeal” of hogs. Agricultural societies often feed plant food wastes to animals, while many industrial societies process by-products of animal slaughter into livestock feed. Such practices recycle undesired by-products into edible foods and minimize actual food waste. Some societies accept the waste of less-desirable portions of animals and plants as a sign that they have attained a state of affluence and can afford to consume only high-quality items.

#### Food Systems and Food Waste

Postindustrial societies waste food across all stages of the food system. Food production wastes preharvest food through natural disasters, diseases, or pests; harvested food by inefficient collection of edible crops or livestock; and postharvest food in storage or contamination losses. Food processing wastes food in spillage, spoilage, discarding substandard edible materials, or removing edible food parts in inefficient processing. Food distribution wastes food by offering more food than consumers will purchase and then discarding unsold products. Food acquisition wastes food when consumers purchase more food than they use. Food preparation wastes food by removing edible parts of foodstuffs, spilling or contaminating foods, and rendering foods inedible through improper handling and overcooking. Food consumption wastes food by taking larger portions than can be eaten or by spilling food. Digestion, transport, and metabolism of foods in the body waste nutrients through inefficient

absorption, storage, or utilization, thereby failing to use all nutrients that were ingested.

Waste streams in the food system are the by-products of human production and consumption. Garbology, the study of human waste behaviors, identifies food waste as a significant portion of the total human waste stream. Food waste comprises about 10 percent of the total municipal solid waste streams in postindustrial nations and higher percentages in societies lacking mechanized refrigeration and durable packaging.

The four principal methods of disposing of food waste are dumping, burning, minimizing, and recycling. Dumping is the most common method of food waste disposal, but it may create sanitation and landfill problems. Burning food waste is convenient and minimizes the amount of solids needing to be disposed, but burning reduces air quality and is banned in many places. Minimizing food waste occurs through food trades, gifts, donations, and conservation during preparation and after consumption, such as reusing leftovers. Recycling often involves feeding food waste to livestock or composting food refuse. Compost can be used as fertilizer to grow more food, reducing the absolute food waste.

### The Cost of Food Waste

Food waste significantly impacts environmental, economic, and community health. The accumulation of discarded food in landfills contributes to air and water pollution, and the burning of food refuse also affects air quality. Economic and nutritional losses are incurred from the calories lost in discarded food as well as from the energy and materials used to transport food waste to landfills. Wasted food means fewer nutrients are available for human consumption, which jeopardizes community food security.

There are also costs associated with the use of salvaged foodstuffs. For example, feeding animal slaughter by-products to livestock has caused outbreaks of bovine spongiform encephalopathy (BSE) and hoof and mouth disease in several European nations. Consumption of leftover foods that were not prepared or stored properly is implicated in many cases of foodborne illness.

### Historical Changes in Food Waste

Historical transformations have changed the type and amount of food waste generated. Hunter-gatherer cultures often discarded bones as their primary food waste. The development of agriculture added more plant materials to the food waste stream. Industrialized agriculture increased organic waste by-products from large-scale food processing. Increased population growth and urbanization multiplied and concentrated the amount of food waste, which was increasingly dumped as the cities that generated waste became located farther from agricultural areas.

Historical shifts occurred in the conception of food waste. The term “garbage” originated in the French word for entrails and once referred exclusively to food waste. Later the word signified all refuse, since food waste embodies the most unacceptable characteristics of solid waste, putrefaction and attraction of vermin.

Material prosperity reduces the economic necessity for food conservation and reuse, and conspicuous consumption and disposal are demonstrations of social status. Food in postindustrial societies is inexpensive relative to total income, and wasting food is increasingly accepted. Technology that improves the durability of foods, such as plastic packaging, has reduced food waste from spoilage but has created a new waste problem as food packaging contributes more to the waste stream than food itself. Regardless of consumption and disposal practices, the growing world population has increased food waste.

**FOODWAYS.** The term “foodways” refers to the connection between food-related behavior and patterns of membership in cultural community, group, and society. In its most general usage, “foodways” refers to the systems of knowledge and expression related to food that vary with culture. For example, in modern America, foodways continue to represent cultural diversity within an increasingly interwoven society. In specific usage, “foodways” refers to those food-related behaviors that are believed to identify the primary cultural attributes of an individual or group of individuals; for example, it is in their foodways that Northern Italians are most easily distinguished from Southern Italians and Sicilians.

The first American usage of “foodways,” without attribution of coinage, occurs in writings of the folklore initiative within the cultural New Deal—the program of civic reinvestment created by the administration of President Franklin D. Roosevelt in the early 1930s to combat the effects of the Great Depression. In a host of anthology publications, the publicly supported folklore work of the Federal Writers’ Project celebrated American “stuff”: traditional culture more easily identified by

The Makah Tribe prepares salmon for Makah Day Dinner, Neah Bay, Washington. COURTESY OF THE NATIONAL ARCHIVES AND RECORDS ADMINISTRATION.

its prevalence than its longevity. The director of the project's folklore activities, Benjamin Botkin, instructed fieldworkers to gather the evidence of tradition and creativity among America's living regional, ethnic, occupational, and spiritual communities—work songs, the calls of street vendors, festivals, tall tales, superstitions, and foodways.

In this context, foodways is a silent member within a category of expressive genres; like a festival, it is a “performed” tradition whose “texts” are activities that can be observed, and perhaps sampled, but are as emblematic of the people who produce those texts as the more conventionally recognized folk expressions that comprise collections and anthologies of published folklore. Botkin and his contemporaries also used the term “foodlore” on occasion to refer to foodways since, like folklore, it is a canon of shared beliefs or “lore” that is widely held but limited to a certain culture or situation.

Like its kindred terms “folkways” and “lifeways,” “foodways” often echoes the popular anthropology of the 1950s—language carefully, if transparently, tailored to avoid infection by ethnocentrism and tuned to the broadest level of cultural comparison. Foodways is seen as a component of every culture, large or small, but one among several components artificially constructed at a level of analysis and comparison, just above the degree of particularity that might enable it to be easily understood. In its specification of the edible universe, foodways implies other categories containing elements equally innocuous yet laden with meaning: “shelterways,” “clothesways,” and perhaps “homeways,” “workways,” “schoolways,” “healthways,” “leisureways,” or even “deathways.” Each of these terms is logically sensible, but only “foodways” found its way, if by a slim thread, into contemporary usage.

The term “foodways” survived a period in folklore studies, roughly from the mid-1950s into the early 1970s, when what is now generally referred to as “material cul-

ture” in the United States did not rank as highly as the spoken word and the performed arts within the canon of folk expression. It is largely through the efforts of Don Yoder and Warren Roberts that the term was carried from one generation to another, from a period of relative low American academic interest into the current state of broad, heightened engagement.

In “material folk culture,” the summary phrase of Henry Glassie's broad and renewing scholarship, foodways found revived utility in folklore studies. At the University of Pennsylvania and Indiana University, respectively, Yoder and Roberts prepared two generations of students to uphold broad applications of the term “tradition” (that is, inclusive of material folk culture) in their research. Since the late 1960s Yoder has documented the bearers of Pennsylvania's traditions, including those engaged in foodways, for the annual Pennsylvania Folklife Festival—an early example of collaboration between scholars and the general public that would arise later at the national level.

Since the 1970s, the percentage of American folklorists entering academe has been small in comparison to the number working in government-supported positions, located in arts-granting agencies, archives, and libraries as well as in foundations that are actively supporting the application of research to social issues. In both research and public programs, the early twenty-first-century generation of folklorists, more than half of whom were students of Yoder and Roberts, have found material expressions of tradition particularly useful in demonstrating the resilience of folk culture, the fundamental—and key—assertion of folklorists involved in public education.

In the 1980s, as the growing number of government-based programs continued to exercise their commitment to inclusion, many sought to engage recently emigrated peoples from Southeast Asia and Central America as nascent communities. With often limited resources, and language and translation challenges to contend with, a number of folklorists found in foodways a common ground for the presentation and comparison of contemporary tradition in action. In 1969, the Smithsonian Institution's annual Festival of American Folklife—whose advisory board over the years has included Yoder, Roberts, and Glassie—first presented foodways among festival programs that focused upon featured states or regions, ethnic communities, and occupational groups. Since its inception, the festival has included foodways as a way of focusing upon traditionally acquired skills and shared community values.

At the Smithsonian, the presentation of foodways in a festival setting became a model—a work-in-progress—that was emulated by state folklife program coordinators and festival directors. Built upon a foundation of field research that placed culinary traditions within the context of folklife genre, festival foodways presentations co-opted

the “cooking show”—a presentation model made familiar by county fairs, food stores, and television. Here folklorists interviewed traditional cooks in the midst of preparing food and defined, in a way that few other public programs could, the concepts of observation and imitation, informal apprenticeship, and shared standards of appropriateness and taste.

In the early twenty-first century, foodways has generated little scholarship; however, many scholars have focused upon the cultural exchange within so-called food events, often attending to customs found in large-scale and socially significant occasions. Others, particularly those who work in both academic and public sectors of the discipline, have successfully identified matters of cultural consequences found in foodstuffs that are rapidly being depleted in their natural supply by commercial expansion into formerly wild areas. Folklorists Suzi Jones and Lynn Martin Graton, working in Alaska and Hawaii, respectively, have used the concept of foodways to describe and explain native and immigrant communities, natural resource management, and the viability of folk cultural processes.

There is both opportunity and need for more comprehensive foodways scholarship, the reappraisal of food-related traditions as a medium for creating cultural identity, and attention to the responsibilities of active tradition-bearers as teachers, conservators, and innovators. With improved standing in the American academy and the well-earned support of government agencies, foodways is poised to accommodate and frame the rapidly converging interests of scholarship and civic engagement.

## FOOD AND CUISINE IN FRANCE

In 1826 a famous French gastronome, Brillat-Savarin, wrote among other things: “Animals feed, humans eat, but only those with refined taste dine,” and “The creation of a new dish brings more happiness to humanity than the discovery of a new star.” These two aphorisms are fundamental to an understanding of French attitudes toward food. On the one hand, food is not simply a source of nourishment, nor is it something everyone “naturally” appreciates. Only by cultivating discrimination (being attentive to tastes, colors, and textures) will food leave the realm of biological necessity and attain sensual heights. Secondly, creation is both essential and beneficial to society. It is the chef’s duty to create, to advance the art of cookery and in so doing, provide pleasures that surpass those associated with more abstract achievements.

We will return to the importance of these two concepts later, since they are directly related to the prominent place French cuisine occupies in the world today. Before doing so, however, a look backward will help place French cuisine in a greater context and allow us to address several sensitive issues concerning its “birth” and evolution.

### The Italian Controversy

An oft-repeated story maintains that French cuisine emerged from the “dark ages” of primitive eating only when Catherine de’ Medici brought her Italian cooks to France in the mid-sixteenth century, for her marriage to Henry II in 1533. The French being more than apt students, the story goes, not only learned their lessons, but quickly surpassed their Italian masters in the art of fine cookery and . . . *Voilà!* French cuisine was born.

This legend has been repeated in popular histories of cooking for centuries, even in France. It was first evoked in 1739 in the preface to an innovative cookbook attributed to François Marin, *Les dons de comus*, where it is stated: “The Italians civilized all of Europe and it is they, without a doubt, who taught us how to eat. . . . For more than two centuries the French have enjoyed good cooking, but rest assured, dishes have never been as delicate, as expertly prepared, or better tasting, than they are today.” A similar point of view is expressed by Le Chevalier de Jaucourt who authored the article on cuisine in Denis Diderot’s famous *Encyclopédie* published in the 1750s:

The Italians inherited the art of cookery from the Romans; it was they who introduced fine food to the French. . . . During the reign of Henry II, cooks from beyond the Alps came and settled in France, and we are eternally indebted to this motley band that served at Catherine de Medici’s court. . . . The French, finely attuned to the flavors that should dominate in each dish, quickly surpassed their masters who were soon forgotten. From that moment on, as if they had successfully met the challenge of stressing what was important, they could pride themselves in the knowledge

that the taste of their cuisine had surpassed that of all others and reigned supreme in opulent kingdoms from North to South.

Thus, the simple cooking of ages past, having become more complex and refined from century to century, has today become a subject of study, a complex science about which numerous treatises constantly appear under titles such as *Le Cuisinier françois*, *Le Cuisinier royal*, *Le Cuisinier moderne*, *Les Dons de comus*, *L'école des officiers de bouche*, and many others, each one teaching a different method, which proves how futile it is to attempt to re-

duce to an established order what human beings, with their whims and changes of taste, search, invent, and imagine in the preparation of their food.

We will treat these points separately, starting with the reference to Catherine de' Medici and the Italian influence on French cuisine. Both of these eighteenth-century authors agree that the French have enjoyed good cooking "for more than two centuries," that is, since the sixteenth century. In fact, long before the young queen arrived in 1533, numerous sources bear witness to the sophistication of French cuisine.

Starting in the early fourteenth century, manuscript cookbooks were being written in France, one of which became extremely popular. This book, simply known as the *Viandier* (the term *viande* [meat] at that time referred to all eatables, hence a *viandier* was simply a cookbook) was said to be the work of one Taillevent, a chef in the royal kitchens of Charles V. The recipes we find in the *Viandier* are as rich and varied as those in contemporary Italian, English, German, or Spanish cookery manuscripts. This said, French cooks do not appear to have had a greater reputation than those in other European countries. They served dishes common to an “international repertoire” as well as some specific to France.

The situation seems to change in the sixteenth century but not in the way our two eighteenth-century authors suggest. Although a new generation of French cooks did rejuvenate cooking in France, the dishes they propose owe little or nothing to the Italian cuisine of the time, the style of which was radically different. Indeed, the earliest published cookbooks are German and French, not Italian, and barring an Italian dietetic work by Platina published in the 1470s that included some recipes from some fifty years earlier, not one Italian culinary treatise is translated into French. At a time when Catherine de’ Medici was still a baby, travelers, including Italians visiting France, claim that French cooks are the best in Europe, and Rabelais, the most gourmand of writers, clearly prefers French dishes to those of any other nation since he frequently mentions those specific to the national repertoire in his gargantuan menus. In fact, there is no proof that Catherine de’ Medici even brought her cooks with her to France!

No author living in the sixteenth century mentions the supposed superiority of Italian cookery, although Montaigne does marvel at the eloquence and precision of an Italian *maitre d’hôtel* describing the art of banqueting, and the expertise of Italian gardeners, confectioners, and carvers is not only recognized, but admired and copied. Nevertheless, notwithstanding the esteem in which Italians are held in the accessory arts of serving and confectionery, it is not until two centuries later that any hint of the so-called Italian influence on French cuisine per se appears in print. Be that as it may, French cooks do not achieve a clear dominance in the kitchens of Europe until the mid-seventeenth century.

### The Beginnings of French Hegemony

Neither Marin nor Le Chevalier de Jaucourt gives a specific date for the rise of French cuisine. The latter does indicate that the French had “surpassed their masters” in the seventeenth century by including three seventeenth-century cookbooks (*Le Cuisinier françois*, *Le Cuisinier royal* and *L’école des officiers de bouche*) in his list of treatises devoted to the culinary arts. One of these books, *Le Cuisinier françois* of La Varenne, is the first to document the radical changes French cooking had undergone since the end of the Renaissance. Published for the first time in 1651,

La Varenne’s book would be translated into several languages and remain in print for over one hundred years. In the preface to the English translation of 1653 we read, “Of all the cooks in the world, the French are esteemed the best,” and from that time forward French predominance in the kitchen will continue its almost uninterrupted ascendancy.

A partial explanation for the influence of French cuisine lies in its vitality. The best professional chefs feel a duty to improve on the work of their predecessors in order to “advance” the art of cookery. Not only do they create new dishes, their cooking embodies new attitudes toward food, which often spread with the dissemination of the dishes they have invented. Over and over again, a new philosophy of cookery emerges, often in conflict with that of previous generations, always claiming to mark significant “progress” in the culinary art. In the eighteenth century, for instance, devotees compared the cooking of their *nouvelle cuisine* to alchemy, claiming to distill the essence of taste from the ingredients employed. A century later, a new generation of chefs led by Antonin Carême saw the cook more as an architect than a chemist. They encouraged the creation of monumental assemblages and developed a family of basic sauces, some of which are still in use today.

In turn, Auguste Escoffier in his *Guide culinaire* of 1903 rejected the elaborate cuisine developed by Carême, claiming that the “fast pace of modern life” no longer allowed chefs the leisure to prepare elaborated displays, and argued for a simplification of cuisine. It should be noted, in this context, that Escoffier was the first chef to obtain international recognition and to father a new school of cookery who did not work in a private home. Whereas previously the greatest French chefs all worked in aristocratic households or in royal kitchens, Escoffier built his reputation as a hotel chef at the Savoy Hotel in London and later at the newly created Ritz Hotel in Paris, before returning to London to the kitchens of the Carlton Hotel as an internationally acclaimed celebrity whose writings would form the basis of French cooking throughout the greater part of the twentieth century.

### Gastronomy and Gastronomes

Food and cooking alone do not explain France’s reputation in culinary matters. To recall Brillat-Savarin’s words, “only people with refined taste know how to dine,” and the French have not only cultivated the art of cookery but have long considered it an integral part of their culture: how one eats is as important as what one eats. Indeed, the French claim that they invented gastronomy and linguistically, this is certainly true. The term first appears in the title of an epic poem, *La Gastronomie* by Joseph Berchoux, published in 1803, its four cantos treating respectively the history of cuisine in antiquity, the first service, the second service, and the dessert of a banquet. The word rapidly came to designate the study of food and cookery as an art; those who excelled in this

study, and for whom gastronomy was a central feature of their existence, were “gastronomes.”

The gastronome was defined as a critical observer of the chef's work—not a chef. As professionals, gastronomes became food critics, the earliest of whom in the western world appear to be French. Among them, Grimod de la Reynière leads the list as the inventor of a new branch of literature with the publication of his *L'almanach des gourmands* from 1803 to 1812. In this yearly journal, he reviewed restaurants and published the results of tastings aimed at selecting the best artisans and products of his day, beginning a tradition of searching out quality that remains very much alive in the French mentality today.

### *L'exception française*

One has only to contemplate the ferocious aversion of French consumers to hormone-fed beef and veal, to genetically modified food plants and the standardization of food in general, to understand that their relationship to food goes far beyond just eating—much to the bemusement and exasperation of France's trading partners. And where else but in France would the Education and Culture Ministries sponsor a national inventory of traditional food products, or classes teaching children how various foods are made and how to appreciate different tastes, smells, and textures?

The French approach to cookery, the institutions developed by its proponents and the gastronomic culture it glorifies have all contributed to the preeminence of French cuisine. Indeed, the very use of the term “cuisine,” when applied to the food of another nation, implies that it has gone from simply being cooking to something more refined and complex—something closer to the French model. Naturally, the culinary superiority of France has been challenged in the past and continues to be challenged today, but no other cuisine has had such a sustained influence on the cooking practices of its neighbors, nor can any other claim to have exerted as universal an impact on professional cooks around the world, as that which developed and continues to evolve in France.

## NORTHERN FRENCH CUISINES

The Loire River has long served as a divide between northern and southern France. It runs from Nantes on the Atlantic coast to the south of Burgundy, where it veers south at Pouilly, though the French mentally continue the division line eastward to Geneva. Roughly half of France is north of the Nantes-Geneva line, including Brittany, the château country (Orléans to Tours), Normandy, Paris and the surrounding area known as Île-de-France, French Flanders, Alsace, Lorraine, Burgundy, and the Franche-Comté.

Farmers here are basically well-off. The wheat fields of the Beauce, just south of Paris, produce the finest wheat in France, Normandy is famous for its beef and cheese, and the lambs that graze near the sea in Brittany and in Picardy are among the most esteemed in France. Paris itself was once surrounded by vast gardens that supplied the capital's needs.

### Beer, Gin, and Sugar Beets

Running along its most northerly perimeter and extending out to the tip of Brittany is France's longest coastline. From the English Channel to the Atlantic seaboard, fishing has always been a major industry. Herring was the dominant fish along the northeastern part of the Channel, and today salted and smoked herring are still a specialty there. French Flanders, however—like neighboring Belgium, with which it has strong cultural ties—does not spontaneously come to mind as a gastronomic haven. Coal mining was a major industry here, and those who survived the backbreaking work often sought relief in taverns and bars. Beer and hard liquor were consumed in great quantities, and a French version of gin (*genièvre*) wreaked havoc on the health of those who overindulged. It is therefore no surprise that this province holds the sad record of having the highest rate of cirrhosis of the liver in France.

One can nevertheless find something positive here: nowhere else in France is there as great a variety of traditional beers, of every conceivable taste and ranging in color from rich brown to amber, blond, and white. Not surprisingly, beer is the perfect accompaniment to the hearty local cuisine, whether one of the many forms of herring, a Flemish hotpot (*bochebot flamand*), or a pungent Maroilles, “the most delicate of strong cheeses.” A by-product of beer production, brewer's yeast, also contributes to the character of the pastries, many of which use raised doughs, such as the light and airy Flemish-style waffles (*gaufres flamandes*) or briochelike cakes with names like *craquelin*, *cramique*, or *couquebotrom*.

Traditional ceramic terrine for *Alsatian Hasepfeffer (civet de lièvre)*. Poterie artisanale Gérard Wehring, Soufflenheim, Alsace (France), 1998. Rack of hare is baked in wine and gingerbread crumbs in this elaborate earthenware vessel, which also doubles as a serving dish. ROUGHWOOD COLLECTION. PHOTO CHEW & COMPANY.

The North is also the largest sugar-producing region of France. It has been ever since the British navy imposed the Continental blockade at the beginning of the nineteenth century, depriving France of cane sugar from its overseas colonies and prompting Napoleon to reward anyone who could apply a newly-discovered technique for producing sugar from beets on a commercial scale. The North quickly became a center of production of the precious commodity, and it is surely no coincidence that this is the only region where people use brown sugar (called *vergeoise* here), not only in desserts like the sumptuous sugar tart (*tarte au sucre*) with its light or dark brown-sugar filling, but in savory dishes prepared *à la flamande*, including the local blood sausage (*boudin*), sweet-sour red cabbage (*chou rouge*), and beef stewed in beer (*carbonade*).

### Foie Gras and Sauerkraut

Like the ties between French Flanders and Belgium, Alsace, in the northeasternmost corner of France, shares many traits with Germany, its neighbor across the Rhine. Up until the treaty of Westphalia in the mid-seventeenth century, both Alsace and adjoining Lorraine were part of Germany. In the course of ensuing wars, they went back and forth between France and Germany until the end of World War II. As a result, trade with Germany has long

been an important source of income for this region, as has tourism, which has increased in the course of time.

In this land of lager beers, *bretzels* (pretzels), and sausages—where white wines have names like Edelzwicker, Sylvaner, Riesling, and Gewürztraminer—Alsatian culture at first seems purely Germanic. Fat white Alsatian asparagus, which originated in Germany, is a springtime favorite served with slices of smoked ham and Alsatian Riesling. Even mustard is different here. Unlike the sharp Dijon-style mustard preferred elsewhere in France, the white mustard seeds used in Alsace result in a truly sweet mustard that reigns on virtually every table, as in Germany. The celebration of Saint Nicholas Day (6 December) is as important as Christmas in both places. In Alsace, it provides the occasion for making gingerbread effigies of the good bishop and *Mannala* (little man), a doll-shaped cookie associated exclusively with this day.

Not everything in Alsace has a German origin, however, and Alsatians proudly assert their differences with their imposing neighbor to the east. Not only are their wines and beers lighter, but a specific repertoire of dishes and a French penchant for fine gastronomy all distinguish them from their German cousins. A favorite Alsatian specialty that does not seem to have a German equivalent is *Bäckeoffe*, made by marinating beef, pork, and lamb in

white wine and baking them slowly for several hours with sliced potatoes and onions in a special earthenware terrine. Even sauerkraut is prepared so differently here—braised in Alsatian white wine with smoked, salted, and fresh cuts of pork and served with additional Strasbourg sausages and liver dumplings—that Germans cross the river in droves to enjoy *choucroute à l'alsacienne* as a special treat.

The great cheese of Alsace is Muenster, a French-style soft, creamy cheese, albeit served with a decidedly un-French accompaniment of caraway seeds (called *cumin* here). Alsace is also the home of *foie gras*, a quintessentially French specialty that, curiously enough, appears to have been introduced by the large Jewish population that settled here. Over the centuries, the Jews perfected the art of force-feeding geese to increase the quantity of fat, to be used for cooking since pork fat was prohibited by their religion. The enlarged, buttery livers or *foie gras*, a by-product of this operation, had become a highly sought-after specialty by the eighteenth century. Unlike southwestern France (the site of Jewish immigration from Spain), where *foie gras* is most often baked simply in a terrine, the livers are traditionally baked in a pastry shell in Alsace.

### Baba and Quiche

The Germanic influence is much less evident in neighboring Lorraine, where specialties more closely resemble those encountered elsewhere in France. One could name the *potée lorraine*, a poached salt pork and vegetable dinner very similar to the ubiquitous beef-based *pot-au-feu*, the *macarons* from Nancy, or the *madeleines* from Commercy. Another product specific to Lorraine, and the emblem of the region, is the *mirabelle*, a small yellow plum that is enjoyed eaten on its own, distilled to produce an aromatic brandy, made into preserves, or baked into a tart.

Lorraine is also the home of one of the best known specialties in all of France—*quiche*. Mentioned as early as the sixteenth century and initially made with a simple filling of eggs and cream, it was prepared only in the region until the nineteenth century, then started to spread to the rest of country. Today the word, and the pastry, can be found around the world with a bacon-studded filling, an early-twentieth-century variant on the original, meatless filling rarely encountered today.

Like French Flanders and Alsace, Lorraine is beer-drinking country, where many pastries are made with egg- and yeast-rich doughs. The most famous of these is the *baba*, a light, raised cake with raisins. It is derived from a cake of the same name that was introduced in the eighteenth century by the exiled Polish king, Stanislas Leszczynsky, whose daughter, Marie, married King Louis XV of France. As Duke of Lorraine, Stanislas held court in Nancy, where local bakers adopted and perfected the *baba*. By the beginning of the nineteenth century, its fame had spread to Paris, where a pastry chef named Stohrer (whom many believe was from Lorraine) added the final

touch of making individual *babas* and dousing them with rum.

### Smoked Meats and Hefty Cheeses

Directly south of Lorraine is the mountainous region of Franche-Comté, sandwiched between Switzerland and Burgundy. It is a land of hilly, green pastures that produce some of the finest cheeses and meat products in all of France as well as some of the country's most unusual wines. The mountain cheeses, made from the milk of the local Montbéliard cow, range from the creamy *vacherin* of the Mont-d'or, encircled with a strip of spruce wood, to large, hard-pressed wheels of *comté*, the French version of gruyere. Every bit as fruity as its more familiar Swiss cousin, *comté* improves with age. Another cheese peculiar to the region is *cancoillotte*, made in the valleys. After skimming off all the cream to make butter, the milk is allowed to curdle naturally, the curds are dried, and the resulting *metton*, as it is called, is broken up and aged until it has become yellow and waxy. To make *cancoillotte*, a piece of *metton* is melted with butter and water and seasoned with garlic or caraway. Definitely an acquired taste, the creamy, pungent *cancoillotte* is a favorite local topping for baked or steamed potatoes, or scrambled eggs.

Unlike their treatment in most of France, meat products are traditionally smoked here, rather than simply salted and dried. This preference is related to the structure of the typical farmhouse of the area, built around a large central chimney called a *tuyé*. The ham from the Haut-Doubs, the sausages from the towns of Morteau and Montbéliard, and an unusual smoked beef tenderloin known as *bresi*—to name only these few—are among the finest *charcuterie* in France.

As for the wines, the most striking are the whites, made with a local grape variety, the *savagnin*. Their almost sherrylike taste is surprising at first but perfect with the *charcuterie*, cheeses, and cream-based dishes from the region, especially those garnished with morel and chanterelle mushrooms from the Jura mountains. The most astonishing is the “yellow wine” (*vin jaune*) produced near the village of Château Chalon. Always served at room temperature, it can be aged for up to a hundred years, and its particular fruit and walnut flavors are unique.

### Snails, Wine, and Aperitifs

To the west of Franche-Comté lies Burgundy. The most famous dish associated with the region, *boeuf bourguignon*, combines wine and beef, two of Burgundy's most valued resources. Though wine comes immediately to mind when Burgundy is mentioned, there are few vineyards in the southern part of the region where equally famous white cattle are raised on small farms near the town of Charolles. A very large breed with tender, lean meat especially well suited to grilling and roasting, Charolais beef has few rivals in France, and the breed is now raised in some seventy countries worldwide.

Driving north on the road back toward Paris, one sees multicolored tiles covering rooftops in the valley that runs through some of France's most prestigious vineyards. There are virtually no imposing estates here, and the wines take their names from the towns, the most famous of which lie along the stretch of the N7 highway between Chalon-sur-Saône and Dijon: Chassagne-Montrachet, Meursault, Pommard, Aloxe-Corton, Vosne-Romanée, Vougeot. . . . Producers live in simple farmhouses and tend small plots of land, so one must know the names of the specific growers whose style one prefers. Production is small compared to Bordeaux and prices are, on the whole, higher.

For many, the food most associated with Burgundy is snails, once plentiful in the vineyards. Naturally, if they were not gathered, they feasted upon the precious grapes—a sort of eat-or-be-eaten situation. Burgundians long ago chose the first option, consuming them with such gusto that the local snail is now an endangered species that can be gathered for personal use, but not marketed. The large Burgundian snail (*Helix pomatia*) is harder to raise than its southern cousin the *petit gris* (*Helix aspersa*), so the majority of the *escargots de Bourgogne* sold in France are shipped alive to Burgundy from such faraway places as Turkey, where they are still plentiful in the wild and do not fit into the national diet.

In the upper end of the region, Dijon is famous for several specialties. *Moutarde de Dijon* has been renowned throughout France since the thirteenth century and is an indispensable item in French kitchens. The hot, tangy mustard enters into the *vinaigrette* salad dressing familiar to all, or into sauces of all kinds (particularly those for rabbit and pork), or is served alone to accompany a wide variety of dishes: grilled meats, the homey boiled-beef dinner or *pot-au-feu*, and even French fries, dipped into the mustard pot for an extra “zing.”

*Pain d'épice*, a honey-rich gingerbread loaf, can be bought in shops throughout the city. Often eaten casually in the course of the day, Dijon's *pain d'épice* differs from others in that it is always made with wheat flour rather than rye, more popular in the rest of the country.

*Crème de cassis*, a lightly alcoholic, sweet black-currant liqueur produced in Dijon since at least the eighteenth century, can be sipped on its own, or added to a glass of dry white wine (traditionally from the *aligoté* grape). It was in this latter form that it became enormously popular starting in the 1950s, when the mayor of Dijon routinely served the mixture at public events. As a result, it is now known by his name—Kir—and served as an *aperitif* throughout France.

### Pigs' trotters and . . . Champagne!

Given the celebrity of its wine, whose bubbles are synonymous with elegance, one might believe that Champagne, directly north of Burgundy, is a region with a highly sophisticated cuisine. Nothing could be much fur-

ther from the truth. Although the *pain d'épice* of Reims, the wine capital, has been famous for centuries and the pink ladyfingers made there (*biscuit de Reims*) are the ultimate in refinement, for the most part the cuisine of Champagne is hearty country fare. Particularly well-known is the *charcuterie* of Troyes, most notably the *andouillette*, a tripe sausage served either grilled with mustard or baked with a cream-shallot-mustard sauce. Other regional favorites include the boiled-vegetable and salt-pork *potée champenoise*, and *salade au lard*, a deceptively simple dandelion salad that has become the subject of such hot debate that a local historian wrote a 150-page book comparing the merits of different versions: Should the dandelion greens be cut or left whole? Should the bacon be fatty or lean, smoked or just salted? Should the potatoes be cooked in their skins or peeled? And so forth.

Another humble but delicious specialty from Champagne is grilled pigs' trotters *à la Sainte-Menebould*, delightfully creamy inside and crisp on the outside. Named for the town in which they have been served for over three hundred years, the trotters are simmered for up to fifty hours in an aromatic stock, then breaded, broiled, and eaten—bones and all.

Champagne also shares one very prestigious product with the Île-de-France, the region surrounding Paris immediately to the west. For hundreds of years, the northern half of Brie country belonged to the province of Champagne, with its capital at Meaux. The cheeses from the area have been famous since the fifteenth century, and when made with unpasteurized whole milk, *brie de Meaux* is still among the finest cheeses in France. After the French Revolution, however, Meaux was incorporated into the newly created *département* of the Seine-et-Marne, with its capital at Melun, which was (and still is) part of the Île-de-France. This, of course, did not stop farmers in the Marne *département*, to the east of the new administrative line, from continuing to make “Brie de Meaux” as they had for centuries. In 1980, when the coveted *appellation contrôlée* (Denomination of Protected Origin) status was awarded to the cheese, this fact was taken into account. To this day, a small proportion of the mammoth wheels of Brie that can be seen in Parisian cheese shops come from Champagne.

### Feeding Paris

Along with cheeses from Brie, until very recently the Île-de-France could count on the farmland encircling Paris to come close to meeting the needs of the capital in fruits and vegetables. With the spread of suburbs since the 1960s, virtually all of the orchards and vegetable gardens have disappeared. The peaches from Montreuil and the succulent grapes from Thomery (trained against a labyrinth of sun-heated walls near Paris in order to ripen on all sides) are now a thing of the past, as are the mountains of fat white asparagus from Argenteuil that were once served at the finest tables. Nevertheless, although

the great majority of the once-famous fruits and vegetables developed in the Île-de-France are now produced outside of the region, their names remain, reminding us of the past glory of the cherries from Montmorency, the *champignons de Paris* (button mushrooms first cultivated in the limestone quarries that tunnel under Paris), or the delicate, pale-green dried beans (*flageolets*) from Chevrier.

All of this legendary produce, as well as the finest fish and meat from all around France, was sold for centuries at the equally legendary central wholesale market, les Halles, until 1969, when the demands of a constantly growing population and the paralyzing traffic jams it caused forced it outside of Paris, to Rungis. Nevertheless, the bistros that grew up around les Halles still thrive and continue to serve quintessentially Parisian dishes like steaming onion soup (*gratinée*), calf's head (*tête de veau*) with a tangy vinaigrette or highly seasoned mayonnaise (*sauce gribiche*), or the exquisitely simple but refined *boeuf à la ficelle*, beef tenderloin tied to a string, dipped for only minutes in an aromatic vegetable bouillon, served rare with the vegetables, and accompanied by coarse salt, mustard, and pickles or, for an even more refined presentation, by béarnaise sauce.

In the past, much of the produce that arrived in les Halles came from Picardy, directly north of the Île-de-France and sandwiched between Champagne on the east, Flanders on the north, and the English Channel and Normandy on the west. A rich agricultural province, Picardy's main city, Amiens, is only 137 kilometers (85 miles) from Nôtre-Dame. Parisian connoisseurs could order excellent lamb from Beauvais, duck pâtés (*pâté de canard*) from Amiens, eels baked in pastry (*pâté d'anguille*) from Abbeville in the north, and a wide variety of vegetables long before the existence of modern transportation. Artichokes from Laon, beans from Soissons, peas, and even potatoes were once important "exports," although today they can hardly compete with the same products shipped by train or truck from all over France. The small, moist macaroons from Amiens have been famous for well over a century, and few cakes can match the lightness of the Picard *gâteau battu*, a tall, fluted *brioche* shaped like a chef's hat.

### Camembert and Calvados

To the west of Picardy, green pastures and half-timbered houses welcome you to Normandy. A land long famous for the quality of its butter and cream, Normandy is also a land of great cheeses, and the little town of Camembert can lay claim to producing what is arguably the most famous cheese in the entire country. Curiously, most people don't know that Camembert is a relatively recent invention, as cheeses go. Dating back to the eighteenth century, it is said to be a variant of Brie, and its popularity dates only from the nineteenth century, when railways made it possible to ship the cheese to distant markets. An authentic Camembert is made from unpasteurized whole milk and aged until its white crust is streaked with rust-colored stripes.

Those who associate Norman cooking with butter and cream are often surprised when they encounter another specialty—*tripes à la mode de Caen*. One of the gastronomic glories of the region, the tripe is simmered for hours with carrots, onions, and condiments before a dash of calvados is added as a finishing touch. Made by distilling apple cider (apples are another product indissociable from Normandy), calvados is a popular digestive brandy (*digestif*) both in and outside the region. It is as common as (and generally cheaper than) cognac, although the finest old calvados can equal its more famous rival in both taste and price.

Another unusual Norman specialty is duck—not just any duck, but a special breed developed in Rouen and slaughtered by suffocation so that blood remains inside. Only this duck should be used when preparing *canard à la Rouennaise*. Young and tender, it is cooked and served in a complex manner—which involves crushing the carcass in a specially designed silver press to recover the blood and juices for the making of a sumptuous sauce.

In addition, the Normandy seacoast is historically the site of intense fishing, and many ports are associated with specific fish. Fécamp, for example, was once an important center for the fish-curing industry. Inexpensive and nonperishable, salt cod and herring were in centuries past a staple throughout Europe, particularly sought-after during Lent when meat and poultry were banned. The curing industry has now vanished, but the fresh fish remain. Other ports are known for other specialties: particularly prized are the sole from Dieppe, the shrimp and lobsters from Cherbourg, and the oysters from Etretat and Granville.

### Castles in France

As one travels south toward Orléans and the Loire valley, the culinary landscape changes. After the flat, wheat-growing plains of the Beauce around Chartres, game becomes plentiful, eel stewed in red wine is a popular dish, and white asparagus is abundant every spring. In Orléans, one can sample a delicious quince paste called *cotignac*, already famous in the sixteenth century, and the vinegar made in the city is considered the best in France. Some 37 kilometers (23 miles) south of Orléans lies Lamotte-Beuvron, the birthplace of one France's favorite desserts. It was here, in the modest Tatin hotel run by two sisters, that the famous *tarte tatin*, a rich and buttery caramelized apple tart baked upside down, is said to have been invented.

Nestled in the gentle hills along the Loire River from Orléans to Tours are the extraordinary châteaux built by the kings and high nobles of France. Rabelais was a native son of Chinon, and his love of good food is no wonder in this idyllic region of excellent lamb and poultry, fruity and delicate goat cheeses from Chavignol, Sainte-Maure, and Valençay, and wonderful pork products, among which the *rillettes de Tours*, a creamy, spreadable pâté, has no equal. Not to mention the local wines—light,

One of the oldest restaurants in Paris was the Boeuf à la Mode, which opened in 1792. Shown here is a detail from one of the restaurant's menus in 1919. The scene is intended to evoke an image of the restaurant in its heyday. ROUGHWOOD COLLECTION.

elegant reds from Chinon, Anjou, and Bourgueil, and lively whites from Vouvray, Pouilly, Quincy, and Sancerre—which are the perfect companion to these and other delicacies of the region.

A bit farther back from the river, caves hollowed out of the chalky hillsides are used for growing button mushrooms, and as one wends one's way westward, the lambs are joined by cattle; the Pays-de-la-Loire is the largest beef-producing region of France, providing 20 percent of the total production. Poultry is first-rate, especially in the *département* of the Sarthe, where the capon (*chapon*) from Le Mans has been famous since the sixteenth century.

### Bagpipes and Butter Cakes

Proceeding west, one enters the Breton peninsula, which extends far out into the Atlantic, measuring about 150 kilometers (about 95 miles) from north to south at its widest point, but only half that at its tip. It is a province inhabited by one of France's most independent-minded peoples, who have long fought to preserve their traditional language and culture, descended as they are from

the Celts who fled here from Great Britain during the invasion of the Angles and Saxons starting in the fifth century. Not only are the Bretons trying to preserve their Celtic language, but they celebrate holidays and festive occasions to the sound of bagpipes, as do their Celtic cousins in the British Isles. A separatist movement would like to see this province secede from France, but most Bretons consider themselves thoroughly French and are proud to be so.

Contrary to most of France, virtually no cheese is produced here. The Bretons churn virtually all of their cream into butter which, unlike that made elsewhere in France, is preferred salted. The importance of butter is nowhere better appreciated than in the local pastries, whether in the form of cookies like the paper-thin *galettes* or the crumbly, shortbread-like *palets*, the *gâteau breton* (a sort of cake-sized *palet*), or the inimitable *kouign-amann* (literally, "butter cake"), in which butter and sugar are rolled and folded together in a bread dough that is baked until caramelized. Although cider is the main beverage, this is also the only French province where buttermilk

(*lait ribot*) is drunk, more often than not with savory buckwheat pancakes (*galettes de blé noir*) or sweet wheaten *crêpes*, both spread out to an almost transparent thinness.

Given Brittany's extensive coastline, it is no surprise that the Bretons are a legendary seafaring people. From the sixteenth century onward, countless ships have set out from Nantes, Brest, and Saint-Malo, sailing thousands of miles to fish the great cod banks of Newfoundland. Sardines and mackerel are also plentiful, and, as in Normandy, the salt-cod trade once made towns like Saint-Malo the center of constant activity. Brittany is also a favorite vacation spot for those who wish to escape the crowded beaches in the south of France. Vacationers feast on seafood, particularly shellfish; most notable are lobsters, virtually absent from every other French coast and considered superior to the American variety that lives on the other side of the Atlantic.

Benefiting more than any other part of France from the Gulf Stream, the province has for centuries been renowned for the quality of its fruits and vegetables. In recent years, it has literally been transformed by industrious farmers growing cauliflower, strawberries, and even tomatoes. One vegetable that is especially associated with the region's agriculture is the globe artichoke. Despite competition in recent years from the purple artichoke grown in Spain and southern France, Breton artichokes are still highly sought-after, and plentiful, in markets throughout the country from June to October.

### Northern Riches

Living in the most populated and by far the most industrial part of the country, few inhabitants of the northern half of France have suffered the hardships of those living in the most desolate parts of the south. Farmers in the north have benefited most from the presence of Paris in its center, since the French capital has always been a vast market for goods produced here. The extensive seacoast has been the source of a thriving fishing industry from the Middle Ages until today. Northern France is a patchwork of cultures where beer and cider can be more important than wine, not only on the table but in the dishes as well, although butter and cream are universally employed here. From the rugged, foggy coasts of Brittany to the green, low-lying mountains of the Franche-Comté, this gentle France is a far cry from the sun-baked fields, the olive trees, and the snowy heights of the Pyrenees and Alps only a few hundred miles to the south.

## SOUTHERN FRENCH CUISINES

Broadly speaking, southern France extends southward from the Loire River to the Mediterranean, and eastward from the Atlantic coast to the Alps along an imaginary line running from Nantes to Geneva. Numerous cultures and cuisines coexist in this vast area. Walnut oil and goose fat in the southwest give way to olive oil along the Mediterranean coast which, in turn, yields to butter in the foothills of the Alps.

Most of southern France is covered with grape vines but the wines they produce differ greatly from one another. South and east of the prestigious Bordeaux châteaux lie the vineyards that produce the earthy reds of Madiran and Cahors. Along the Mediterranean seacoast, the lighter reds and whites of Languedoc-Roussillon blend into the rosés of Provence. At their juncture, the Rhône Valley runs north, with full-bodied wines that range from the rich reds of Châteauneuf-du-Pape and Hermitage to the flowery white Condrieu, a far cry from the crisp white wines of Savoy, nestled in the Alps.

Although Bordeaux on the Atlantic seaboard, Toulouse in the southwest, Marseilles in the south, and Lyons in the northern Rhone Valley all function as regional capitals in southern France, none of them acts as a center for concentrating wealth and stimulating production as Paris does in the north. On the whole, the south is more varied from both a physical and culinary point of view.

### Of Oysters and Mussels and Goat Cheese Cakes

Proceeding southward along the Atlantic coast from Nantes to Bordeaux by way of La Rochelle, one encounters two provinces rarely visited by the casual tourist: Poitou and Saintonge. Grouped together into the administrative region of Poitou-Charentes, this is a transition area that shares some aspects with the north of France and some with the south. One of the most famous butters in all of France, *beurre d'Echiré*, is produced here and butter-based dishes are common, though they in no way resemble those made in Brittany or Normandy. One of the most popular is *embourré de choux*, literally "battered cabbage," made by crushing boiled cabbage with a fork, then stirring in a healthy amount of fresh butter. Steamed new potatoes from the Île de Ré, served with butter and sprinkled with the sea salt (*fleur de sel*) also produced on this island off La Rochelle, are another treat far more sumptuous than the simplicity of the preparation would lead one to imagine. And the local goat cheese, called *cabichou*, although delicious on its own, is also turned into desserts, whether the tartlike *fromageau* or

the astonishing *tourteau fromagé*, with its jet black, rounded top and light, moist inside.

Curiously enough, the food most frequently associated with the Charentes is the snail, so much so that people here are called *les cagouilles* (snails). They like their snails—not the large Burgundian snail but the smaller, southwestern *petit gris*—grilled over an open fire or simmered in red wine. Mussels, too, are popular, particularly when transformed into *mouclade*, that is, opened over the heat with a little white wine, then finished with cream (and occasionally a pinch of curry powder!). Oysters from the Arcachon basin (*huîtres de Marennes*), both sought after and plentiful, are preferred raw on the half-shell here with an accompaniment of grilled sausages and a glass of white wine.

### From Lamprey Eels to Foie Gras

South of the Charentes is Bordeaux. The wine capital of France, this city is also a major port with numerous links to the sea. Given its location on the estuary of the Gironde River, it is perhaps not surprising that the most emblematic fish of the region are estuary fish: shad, lamprey eel, and sturgeon. The first two swim in from the sea and up the Gironde in the spring and are highly prized by local gourmets who relish grilled shad with a sorrel sauce (*alose à l'oseille*) and prefer their lampreys in a red wine sauce thickened with the fish's own blood (*lamproie à la bordelaise*). In centuries past, however, the sturgeon was the king of fish, not only around Bordeaux but on aristocratic tables throughout France, where it reigned supreme until the end of the sixteenth century. By the end of the nineteenth century, however, the French had also discovered the joys of caviar, which so decimated the wild Atlantic sturgeon population that, since 1982, its fishing has been banned. In recent years, however, a slightly smaller species has been successfully farmed, permitting the curious to once again sample sturgeon and caviar from the Gironde.

South of Bordeaux a once treeless expanse known as the Landes stretches down the coast almost to Spain. Planted with pines over a century ago, it is still sparsely populated but attracts tourists in search of a pleasant beachfront with inexpensive holiday accommodations. In the Landes, and extending inland for many miles, geese and ducks have brought fortune and fame to farmers for centuries. Force-fed until their livers swell to enormous size, they are then sacrificed, producing *foie gras*, a luxury product highly sought after both in and outside the region.

Although *foie gras* is indisputably a French specialty today, it was probably introduced into the southwest by Spanish Jews fleeing religious persecution in the seventeenth century. They had perfected the art of force-feeding geese as a means of obtaining a ready supply of cooking fat (pork fat being prohibited by their religion), much as northern European Jews introduced *foie gras* into Alsace (see Northern French Cuisines). Today, goose *foie gras* is produced on a very small scale, but fattened duck

Legs of lamb rubbed with Provençal herbs (among them, French lavender) roast slowly beside a fire at the Bistro des Alpilles in St. Remy-de-Provence, France. © OWEN FRANKEN/CORBIS.

livers are a major cottage industry. Easier to handle than geese and demanding a much shorter fattening period, the plump ducks also provide locals with two other highly prized specialties: duck steaks (*magret de canard*) and preserved duck (*confit de canard*). The thick steaks, made from the meaty breasts of the fattened ducks, started becoming popular in the 1970s when local restaurateurs began putting them on their menu. Previously they were salted, then simmered in a cauldron of fat until completely tender, like the rest of the bird, to make *confit*, which could be kept for several months packed in their cooking fat in large stoneware jars. Today, this ancient technique is carried one step further, and the *confit* is subject to a second preserving process by being sterilized and canned. Jars of *confit* can be kept on a kitchen shelf for many more months than the traditional preserve and are sold at roadside stands all year round.

The area northeast of the Landes, Périgord, produces perhaps the most expensive delicacy in all of France: black truffles. Specially trained dogs and pigs smell their location in the ground since, to this day, no one has found a way to successfully cultivate the elusive subterranean mushrooms, which explains their high price and scarcity even in France. Thinly sliced and barely warmed, truffles can be used to garnish many dishes. They are frequently served with *foie gras* or poultry although many people maintain that they are best with very simple foods—steamed potatoes with butter and salt, or creamy scrambled eggs, for example—or on their own, wrapped in waxed paper and buried in the embers until the truffle has been warmed through.

Although truffles are in season from December to March, they are in such high demand during the holiday season that patient gourmets wait to purchase them until after 15 January when prices drop to more “reasonable” levels. Like *foie gras*, canned truffles also form a

lucrative part of the preserving industry, but neither of these exceptional foods survives the canning process unscathed. Though they are exported in this form around the world, they are in no way comparable to their fresh counterparts, which are rarely available outside of France.

### Nations within a Nation: The Basque Country and French Catalonia

Although only 500 miles (800 kilometers) separate the Atlantic Ocean from the Mediterranean Sea, the culinary traditions that straddle the Pyrenees Mountains along these two seaboards are as different from each other as the people who created them. On the Atlantic coast is the Basque country that extends roughly from Bayonne to Bilbao. Much like the Bretons in the North, the fiercely nationalistic Basques have long demanded independence from both France and Spain and struggle to keep their native customs and unique language alive on both sides of the mountains. They are proud of their “differentness,” which is reflected in their cuisine. Unlike almost any other in France, Basque cookery is marked by a preference for spicy tastes. A special variety of chili pepper grown near the town of Espelette is particularly sought after and used in preparing *piperade*, a spicy tomato stew, most often stirred into scrambled eggs and garnished with a slice of Bayonne ham, or served next to the ham with a fried egg on top. Inveterate fishermen, the Basques were among the first to exploit the great cod banks of Newfoundland in the sixteenth century, and their love of fish is expressed in dishes like *ttoro*, a fish stew, stuffed squid (*encornets farcis*), or sweet red *piquillo* peppers stuffed with a creamy codfish purée. Irouleguy wine is a perfect accompaniment to all these delicacies, unless one prefers to taste the local sparkling cider (*sagar-inoa* in Basque), another specialty of this most remarkable corner of France. And to finish the meal in a typically unusual way, Basques like to serve their famous Ossau-Iraty sheep’s cheese (*fromage de brebis des Pyrénées*), with orange marmalade or black cherry jam from the village of Itxassou and a glass of sweet Jurançon wine from the neighboring Béarn region just to the east.

Another product that arrived from the Americas four centuries ago and took hold in the traditional cuisines of the French southwest along with the chili pepper and its relatives is corn (maize). Originally a replacement for the once popular millet, ground cornmeal is used principally to make a bread (*pain de maïs* or *mesture*), and a thick porridge known variously as *cruchade*, *escauton*, or *millas*, eaten hot as a garnish with any number of stews or allowed to cool, cut into slices, pan fried in butter, and sprinkled with sugar for dessert. Cornmeal quickly became a staple in the peasant diet, and the grain had the added advantage of fattening both ducks and geese much more efficiently than native European cereals.

At the other end of the Pyrenees facing the Mediterranean is another community that takes great pains to preserve its proud traditions. Catalonia, a powerful na-

tion during the Middle Ages, straddles the border between France and Spain, roughly from Perpignan to Tortosa, south of Barcelona on the Costa Brava. The Catalan language is still spoken on both sides of the Pyrenees, and Catalan nationalists have long argued that the two provinces should be united again to make an independent border state. Much of Catalonia hugs the Mediterranean and it comes as no surprise to find that the people excel in preparing seafood dishes of all kinds, among which are the *bullinada* (a fish soup similar to bouillabaisse), the *llagostada* made with spiny lobster (*langouste*), or the *pinyata* from Collioure, which includes everything from octopus, shellfish, and eels to red mullet cooked in a tomato sauce. Fresh anchovies, sardines, and tuna are also used to create many a Catalan dish but for centuries, the tiny village of Collioure, nestled near the Spanish border between the foot of the Pyrenees and the Mediterranean sea, has made a specialty of salting them. Used as condiments, or eaten alone, the salted anchovies (*anchois de Collioure*) are especially esteemed and used extensively in Catalan cooking. Unfortunately, they have become a rarity, and canned or salted anchovies from North Africa tend to take their place.

Fish are not the only strong point of Catalan cooking. It also boasts a wide range of pork products including an air-dried prosciutto-like ham called *gambajo*, and sausages (*embotits*) of all kinds that fall generally into two categories: *boutifarra*, or blood sausages, and *llonganissa*, long pork sausages that can be either fresh (*fresca*) or dried (*seca*). And no meal would be truly complete without *touron*, the multifaceted Catalan sweet that can be anything from white and creamy to crunchy and dark (with lots of almonds or pistachios), or a glass of one of the naturally sweet wines from Rivesaltes and Banyuls, either at the start of the meal or to accompany dessert.

### Cassoulet, Clafoutis, and Cantal

North of the Pyrenees and east of the Landes is a vast expanse that continues the southwestern traditions of *foie gras* and *confit*, and where a third American “immigrant,” the white kidney bean, has become the basis of yet another emblematic preparation, *cassoulet*, traditionally cooked and served in a large earthenware bowl known as a *cassole*—hence its name. As with most legendary dishes, the number of recipes is countless, but two towns claim to have invented it: Castelnaudary, where the beans are cooked only with pork products, and Toulouse, where lamb is added. Both include at least one kind of sausage and generally duck or goose *confit* as well. Although most people consider that the original *cassoulet* was that of Castelnaudary, each has its partisans who religiously defend their local version as the only “authentic” one.

Extending north of Toulouse, toward Limoges, are some of the finest orchards in France, producing the inimitable, plump prunes (*pruneaux*) of Agen, the sweet white grapes (*chasselas*) and greengage plums (*prunes Reine claudes*) of Moissac, and the walnuts and melons of Quercy.

And although the Limousin has long been one of the most destitute regions in the entire country, it can nevertheless lay claim to producing not only some of the finest china in the world but beef, veal, lamb, and pork that are among the best in all of France. In centuries past, the impoverished peasants lived principally on a diet of chestnuts and a large variety of turnip called the *rave du Limousin*, one of the vegetables that is still a must in a true *potée limousine*, a one-pot boiled salt-pork and vegetable dinner. Another essential *potée* ingredient is the *mique* or *farcidure*, a dumpling (either plain or flavored with various leaf vegetables or herbs) originally made of millet flour, then corn flour, but more often today with wheat flour, which has become more widely available in the last half century or so. And no *potée limousine* would be complete without its accompaniment of *moutarde violette*, purple mustard from Brive-la-Gaillarde, which gets its color from the grape must with which it is still made.

By far the most famous of the specialties from this region is *clafoutis*, a Limousine cherry flan that has become a favorite all over France. But beware! In order to preserve the intense flavor of the black cherries and keep them from losing their juice, the people of the Limousin are adamant that the fruits must be baked with their pits!

To the east of the Limousin, in a vast, mountainous area called the Massif Central, lies the Auvergne, another very poor region where the peasants once survived on a diet of chestnuts, dairy products, and black rye bread baked into mammoth, round loaves. Nevertheless, it is a region that can be proud of its gastronomic heritage. Clermont-Ferrand has been famous for its fruit jellies (*pâtes de fruit*) since the sixteenth century, especially those made with apricots that were unequalled even in Paris, according to one early traveler. The sausages and hams made from chestnut-fed pigs and dried in the cool mountain air are sought after nationwide, as are the tiny green lentils from Le-Puy-en-Velay, considered to be distinctive enough to have been awarded the coveted AOC status (*Appellation d'origine contrôlée*) usually reserved for fine wines and cheeses. The *lentilles vertes du Puy* were so famous by the end of the eighteenth century that they were not only shipped all over southern France but as far as Italy, Spain, and Portugal.

Nevertheless, Auvergne's claim to fame, as well as that of the neighboring Rouergue, immediately to the south, is undoubtedly the quality of its cheeses. Most of them are made from cow's milk; among them are bleu d'Auvergne, tender Saint Nectaire, and Cantal, a large, thick cylindrical cheese whose taste ranges from buttery to pungent, depending on its age. When very young, it is used in cooking, often with potatoes in dishes like the crusty *truffade* or the creamy *aligot* that, when properly made, forms a rope when the spoon is lifted out of the pot and must be cut with scissors to be served!

Cantal is made over a large area, with famous variants from Salers in the Auvergne, made from the milk of mahogany-colored cows of the same name, and from

When asked why French cooking tastes the way it does, most chefs will reply "it's the butter." French butter is world renowned and the farmhouse butter from Brittany, shown here, is among the best. © MICHELLE GARRETT/CORBIS.

Laguiole (pronounced lye-ole), made from the milk of the Aubrac breed of cow in the area around Rodez in the Aveyron *département*. But the most celebrated cheese of this area is made from ewe's milk in and around the little town of Roquefort-sur-Soulzon near Millau, south-east of Rodez. In the course of fermentation, the cheese is strewn with crumbs of moldy rye bread, creating the greenish-blue pockets that give Roquefort cheese its distinctive look and taste.

### Olives, Olive Oil, and Honey

Continuing south from Roquefort toward the Mediterranean coast, one passes through almond, apricot, and peach orchards, leaving the domain of lard, goose fat, and walnut oil and entering the realm where the olive reigns supreme. All along the crescent that forms the French Mediterranean coast, olive trees abound. Introduced by the Greeks, olives and olive oil have had a checkered history in Languedoc and Provence. Although the best oil

In an effort to reaffirm regional food identities, village fairs are cropping up all over France. This Renaissance fair at Salon-de-Provence features a rich variety of local pastries as well as reconstructions of Renaissance dishes. © GAIL MOONEY/CORBIS.

has always been a valuable export, in the not so distant past, inferior oil was burned in oil lamps. Even to this day, a green soap known as *Savon de Marseilles* is made from low-grade oils of the region.

Gastronomically speaking, the olives and olive oils of southern France are as varied as wines, as are their uses. At the western end, the inhabitants of Languedoc-Roussillon are partial to the slender, delicate green *picholine* and the darker green, crescent-shaped *lucque* with its almost lemony flavor; in the east, although the wrinkled brown olives from Nyons, in the southern Rhône Valley, have gained national renown, the people from Nice remain faithful to the tiny black olives produced in the hills rising up behind that city's famous pebble beaches. In between, the number of varieties and the ways of preparing them are countless, as are the flavors of black or green *tapenade*, an olive paste spread on toast as an appetizer.

Among the oils of southern France, those made in the Valley of Baux-de-Provence north of Arles, in Aix-en-Provence, in Nyons, and in Nice are the most sought after today. However, because oils can vary widely in taste depending on the variety of olive used and whether the fruits are pressed green or ripe, it is best to sample as many as possible since some go best with steamed vegetables, others with fish, and yet others are better adapted to making sauces, according to personal taste. In this part of the country, not only is olive oil ubiquitous in the preparation of savory dishes, it even enters into traditional pastries such as the *fougassette*, *pompe à l'huile*, or *gibassié*, an enriched hearth bread lightly flavored with orange-flower water that is the most substantial of the thirteen desserts served at a traditional Provençal Christmas banquet, or *gros souper de Noël* (the others being walnuts, hazelnuts, almonds, white nougat, black nougat, figs, raisins, dried apricots, peaches, apples or pears, fresh

mandarin oranges or clementines, a special melon called a *verdau*, and finally, either *calissons d'Aix* or fruit jellies from Apt).

Another southern product with extraordinary diversity is honey, which comes in as many flavors as there are aromatic flowers for the bees to gather pollen from: rosemary, thyme, and lavender from the plains, chestnut, heather, and any number of scrub plants from the hills. Of all these honeys, the most famous historically is that of Narbonne, a small town at the west end of the Mediterranean north of Perpignan, renowned for its incomparable rosemary honey (*miel de Narbonne*) since at least the twelfth century.

### From Nîmes to Bastia

The image of Provençal cooking as based on olive oil, tomatoes, and garlic is a much abused stereotype. For centuries lard was the dominant fat in the southern French kitchen, olive oil being reserved for the many meatless days imposed by the Roman Catholic Church (which explains at least in part its lingering presence in festive pastries). Although garlic has been around since the Middle Ages, tomatoes, now the pride of the region, were not used on a wide scale until the end of the eighteenth century. Therefore, it comes as no surprise to find famous southern dishes that use no tomatoes. A particularly striking case in point is *brandade de morue*, a creamy purée of salt cod from Nîmes flavored with just a hint of garlic and into which warm olive oil and milk have been beaten. Another example is *daube de bœuf*, an aromatic beef stew from Nice in which the bouquet garni always contains a piece of orange peel. Indeed, a great many of the traditional specialties sold in the street markets of Nice and other Provençal cities have not a hint of tomato: *socca*, a large, thin pancake made of chickpea flour; *pissaladière*, an onion-anchovy pizzalike tart with black olives; sardines, either grilled or stuffed with spinach. Among the desserts, one of the most astonishing is the *tourte de blettes* from Nice, a sweet tart filled with Swiss chard greens or spinach studded with pine nuts and raisins. And although vanilla, another newcomer from the Americas, is now a ubiquitous flavoring in pastries all over France, traditional cakes and cookies throughout the south—*fougassette*, *navette*, *gimblette d'Albi*, or the spectacular *gâteau à la broche* (baked on a spit), to name only those few—have remained faithful to lemon peel and orange-flower water, firmly entrenched here for centuries.

A rapid survey of French Mediterranean cooking would not be complete without a visit to Corsica, home of one of the most colorful figures in French history, Napoleon Bonaparte. Nicknamed *l'Île beauté* (the isle of beauty), Corsica became part of France only in 1768, after a forty-year struggle for independence from a thousand years of Italian domination. The local language and products are still heavily impregnated with their Italian heritage, yet maintain their differences. The Italian origin of pork products with names such as *coppa*, *prisuttu*,

and *salamu* is clear, but the excellent quality of the semi-wild Corsican pigs, fattened on the chestnuts and acorns of the island's extensive forests (*le maquis*), sets them quite apart—to say nothing of the inimitable *ficatellu*, a pungent liver-based sausage, grilled when fresh, sliced like salami when dried. The Corsicans themselves subsisted for centuries on chestnuts, and chestnut flour is still used in many local specialties like *nicci* (thin crepes) or *castagnacciu* (chestnut cake). But perhaps the most emblematic products of the Isle of Beauty are *cabri*, baby goat, the high point of every festive occasion, and *brocciu*, the “national cheese of Corsica,” made from the whey left over from the fabrication of other cheeses. Although it may be consumed as is, fresh or aged, *brocciu* often enters into desserts, whether fritters (*fritelle*), turnovers (*pastelle*), or the king of Corsican cheesecakes, *fiadone*.

### The Northeast and Lyons

Just north of Nice the Alps begin, extending all the way to Geneva. The olive groves blend progressively into a land of pasture, cows, and butter. Cow's milk cheeses such as the orange-crustured Reblochon, the creamy Vacherin, or the gruyere-like Beaufort are the pride of the region. Rich potato dishes abound, the most famous being the *gratin dauphinois*, from around Grenoble, where thinly sliced potatoes are baked in cream until brown. To put cheese on top is considered heresy here (but typical of the Savoyard version of the dish made high in the Alps to the north). Another specialty associated all over France with Grenoble is walnuts. The large tender nuts, shipped in their shells throughout the country during the fall and winter seasons, are considered so specific to the area that they have been accorded their own prestigious AOC.

A small pocket of flat land lying roughly halfway between the Alps and the Rhone Valley prides itself on another unique AOC. Called Bresse, this area is familiar to all French gourmets as being the part of the country where the best chickens are raised. The white-feathered, blue-footed *poulet de Bresse* can sell for three to four times the price of other free-range birds. Served in the finest restaurants around the country, it is the only bird to have been awarded AOC status. Once a year the finest specimens are displayed to compete for blue ribbons in Bourgen-Bresse. Capons and pullets are specially fattened, slaughtered, and wrapped tightly in linen to press the wings and legs into the fat, producing a smooth torpedo shape. The slightest flaw, a bruise or tear in the translucent skin, immediately eliminates the bird. The prize winners bring not only prestige but also considerable income to their owners since they are sold at a premium at the conclusion of the fair.

About forty miles (sixty kilometers) southwest of Bresse is Lyons, which prides itself on being “the gastronomic capital of France.” Lyonnaise cuisine is very hearty, with a penchant for extremities, innards, sausages, and lots of onions. Small restaurants, called *bouchons*, perpetuate local traditions and serve such typically Lyon-

naise fare as sheep's trotters salad (*salade de pieds de mouton*), crunchy, pan-fried smooth tripe (*tablier de sapeur*), honeycomb tripe sauteed with onions (*gras-double à la lyonnaise*), pork sausage with potatoes (*saucisson lyonnais, pommes à l'huile*), as well as more refined dishes like pike dumplings with crayfish sauce (*quenelles de brochet, sauce nantua*), or a creamy cheese mixture laced with herbs and a little white wine called *cervelle des canuts*.

### The French Paradox

Each part of France has its own culinary traditions. France's temperate climate, varied topography, different soils, and multiple coastlines combine to make it one of the richest agricultural countries in Europe. Nonetheless, like most industrial countries today, France's culinary landscape is changing. Although some foods like the wind-dried cod (stockfish) still favored in isolated communities in south-central France and in Nice rarely travel far from home, many that were once reserved for festive occasions are now consumed on a daily basis while others, once hardly eaten outside their place of origin, like *confit de canard*, are now readily available in shops and restaurants throughout the country.

The wide variety of French regional cuisines bears witness to the longevity of local cultural traditions—as well as of the country's inhabitants: France enjoys the lowest rate of cardiovascular disease in Europe (ahead of Portugal, Spain, and Italy) and, curiously enough, it is precisely in the southwest of French, the land of *foie gras* and *confit de canard*, that people enjoy the lowest rate of cardiovascular disease in the industrialized world outside of Japan. The famous French paradox. What is the secret? Nobody knows for sure, but goose and duck fat, garlic, and tannic red wines—the staples of the local diet along with a wide variety of fruits and vegetables—are all known to produce substances that protect the heart. Beyond that, the sheer beauty of a French open-air market with its multiplicity of fresh foodstuffs of every possible color and smell, and the enjoyment of savoring them at a leisurely meal with a glass of wine and good company, may provide part of the answer.

## TRADITION AND CHANGE IN FRENCH CUISINE

France is a country with many cuisines. Some dishes are part of a national repertoire and generally referred to as “traditional family fare.” Examples might be *pot-au-feu* (a boiled beef dinner), *gigot d’agneau* (roast leg of lamb), *vinaigrette* (oil and vinegar dressing), or *pâté de campagne* (country-style pâté). From North to South, these dishes can be found in most French homes. A second group of dishes is mainly, or only, encountered in specific regions. Typically based on ingredients native to the region, they include *choucroute* (sauerkraut) in Alsace, *galettes de sarrasin* (thin buckwheat pancakes) in Brittany, *soupe de poissons* (fish soup) or the more elaborate *bouillabaisse* in Provence. Lastly, certain dishes are part of the *haute cuisine* tradition, which includes dishes prepared by chefs both past and present. A vast group, this repertoire is constantly shifting as tastes evolve and culinary trends change. Such things as *Tournedos Rossini* (beef tenderloin topped with *foie gras*), *pêche Melba* (vanilla ice cream and peaches with fresh raspberry sauce), or the more recent *terraine de poissons* (fish pâté) or *salade folle* (a salad of *foie gras* and mixed greens) are all dishes that can be attributed to specific periods of French culinary history, the first two evoking the *cuisine classique* of the early 1900s, the latter two the *nouvelle cuisine* of the 1970s.

### Changing Fortunes

These various types of cuisine are not mutually exclusive. Béchamel sauce, said to have been created by Louis de Béchamel (1635–1688), was quickly adopted as part of the fashionable repertoire of the eighteenth century and went on to become a mainstay of nineteenth- and early-twentieth-century *cuisine classique*; today it is more likely to appear in private homes than on the menu of some trendy chef. *Boeuf bourguignon* has gone from being a “local” to a “traditional family” dish. Other regional favorites, such as *magret de canard* (fattened-duck steaks), a specialty of the southwest, have been adopted by chefs committed to a more creative cuisine. This said, one is more likely to find elaborate French dishes than traditional or regional ones in restaurants around the world. Only a handful of regional specialties (*cassoulet*, *bouillabaisse*, *foie gras*) are known outside the country, and even then they are often misunderstood and misinterpreted. The vast majority of preparations identified with France and upon which the reputation of French cuisine stands are chefs’ creations, some dated and old-fashioned (*sauce béarnaise*, *béchamel*, *crêpes Suzettes*), others more contemporary (salmon with sorrel sauce, tropical fruit sorbets, flourless chocolate cakes).

### La Nouvelle Cuisine

The exploits of fashionable chefs keep French cuisine alive beyond national boundaries and, to a large extent, influence eating habits within France itself. The most recent trend to remodel the way the world and the French think of food is *nouvelle cuisine* (literally, “new cooking”).

Revolutionary in its beginnings, this movement is now thirty years old. Many of the dishes associated with it have lost their shock value and can now be found in modest households around the country. What was this culinary upheaval all about?

In 1972 two French food critics, Henri Gault and Christian Millau, noticed that several young chefs had started serving dishes with a noticeably different style from those of the past fifty years that had been based on Auguste Escoffier’s early-twentieth-century reinterpretation of classic cuisine. As spokesmen for this new generation of chefs, Gault and Millau became vocal exponents of the “new” cuisine, encouraging the rejection of what were now perceived as obsolete standards and the pursuit of innovative dishes that reflected more personal tastes. They wrote and published a sort of manifesto, not too modestly called “the ten commandments of *nouvelle cuisine*,” which not only gave *nouvelle cuisine* a base to grow on, but profoundly influenced the way many people thought about food and its preparation. The principles Gault and Millau propounded were the following:

1. *Reject unnecessarily complex preparations.* This basically meant abandoning many classic dishes that involved a multitude of sauces (each specific to an element in the final presentation), complicated garnishes, and elaborate preparations that sacrificed taste to appearance. Chefs were invited to emphasize the inherent nature of the foods they were preparing, such as by serving a roast partridge as it came from the oven with a light, simple sauce made from its pan juices and a little butter.
2. *Reduce cooking times.* It was better to undercook rather than overcook: green beans would be served “al dente” and fish would be cooked “slightly pink on the bone.”
3. *Use seasonal produce.* Chefs were encouraged literally to shop daily and cook only what was found at the market that day.
4. *Shorten menus.* Greater attention was to be given to a small number of dishes rather than trying to impress clients with a multitude of preparations that could not be given the attention they deserved. This said, *nouvelle cuisine* popularized “tasting menus” that allowed the curious to sample many dishes in very small quantities. These two ideas are not necessarily contradictory since tasting menus are generally served to entire tables only (not individuals), which means that there are fewer dishes to prepare than it might appear.
5. *Do not marinate meats or hang game.* This complemented the first “commandment” which called for respecting the natural tastes of foods. Gault and Millau added that “marinating meat hides its taste . . . if game is hung at all it should only be for a very short time, otherwise its flavor is altered and an undesirable fermentation begins.” They did, however, ac-

cept the use of spices, particularly new and “exotic” ones, such as green peppercorns and fresh ginger, as a means of heightening flavors.

6. *Abandon heavy sauces.* This was a direct condemnation of such classics as *béchamel*, brown sauce, and other thick, flour-based sauces that produce an opaque coating. The idea was to use light sauces made by deglazing the pan juices with a liquid (wine, water, stock, etc.), and swirling in fresh butter.
7. *Promote regional cooking.* Traditional local dishes could be just as exciting as any others—if they had been “reinvented” according to *nouvelle cuisine* principles.
8. *Take an interest in new cooking methods and utensils.* Steamers, “dry-steam” ovens, and time-saving devices such as the food processor and blender should become standard equipment in the professional kitchen.
9. *Be health conscious.* Good eating is not incompatible with a healthy diet. The chef who best embodied this “commandment” was Michel Guérard, who created *cuisine minceur* (literally, slimness cooking) in the late 1970s. In keeping with this principle, chefs were encouraged to give greater importance to a wide variety of fresh vegetables than in the past.
10. *Be creative.* This speaks for itself.

Thanks to the enormous interest the media took in *nouvelle cuisine*, virtually all of the “commandments” had some effect on the way the French cooked and on their attitudes towards food. The principles would be adopted not only by chefs throughout the country but, in the course of time, by the general public, which was anxious to eat dishes more in tune with contemporary aesthetics and dietary concerns and welcomed the simplification of their preparation.

## Beyond Cuisine

Movements such as *nouvelle cuisine* have not been the only force at work on the French diet. Another new term entered the French language at about the same time as *nouvelle cuisine*: *le fast-food*. Hamburgers and hot dogs were no strangers to France, but in the late 1970s American and British hamburger chains started to proliferate. Their success was at least partially due to the low prices they charged and their link with a foreign culture that was then in vogue. Immediately popular with the younger generation, their success was regarded with dismay by parents who lamented that their offspring had lost all interest in traditional cooking and that French cuisine was doomed to disappear. With the passage of time, however, these fears have proved to be unfounded. Despite the ongoing popularity of fast-food outlets among the young, as the youths of yesteryear mature and their incomes increase, they return to *cuisine* via the chefs’ answer to the foreign invasion: the bistro.

The “McDonaldization” of French cuisine is viewed in France as one of the most threatening influences on traditional cooking and eating habits. This protest was staged in July 2000 by the Green Party to protest the opening of the forty-sixth McDonald’s in the French capital. French breads, pâtés, cheeses, and wines were distributed in front of McDonald’s “golden arches.” © REUTERS NEWMEDIA INC./CORBIS.

Bistros, old-fashioned, homey, reasonably priced places, are a French establishment dating from the end of the nineteenth century, but as the twentieth century drew to a close, the term came to be applied to any small establishment serving moderately-priced food—not necessarily “old-fashioned” or in the least “homey.” Chef’s bistros were adjoined to many famous and prestigious restaurants; in these bistros, one could sample toned-down versions of “the master’s” cooking at bargain prices. Specialized bistros also began to appear, with those dedicated to fish cookery becoming particularly popular. Another spin-off of the fast-food challenge to the French palate was the wine bar, where a collection of regional hams, sausages, pâtés, and cheeses, or a small simple dish, could be enjoyed with a glass of wine.

In short, tradition and change constantly find new ways to coexist as each “lost generation” of French diners rediscovers the gastronomy it had so ardently rejected. Just as with *nouvelle cuisine*, the invasion of fast food has enriched and diversified the dining experience and provided yet another opportunity for France to show the world that its cuisine is alive and well—responding to new challenges and incorporating new ideas without losing sight of the foundations upon which it continues to build its reputation.

## WINE AND THE FRENCH MEAL

For the French, wine is not an alcohol but a beverage. Like most beverages, it is generally consumed at meal-times and like bread, it is so much a part of most meals that many French people would not enjoy eating without drinking a little wine. Given its importance and the wide variety of French wines to choose from, they have devised a few simple rules for serving wine:

- White with fish, red with meat
- White before red
- Serve wines in ascending order (the best wine last)
- Drink wines of a region with foods from that region
- Drink reds at room temperature and whites chilled

Of course, the French being typically French, there are exceptions to every rule.

### White with fish, red with meat

For the most part, this rule is respected, especially concerning beef and lamb. But there are important regional differences. In Alsace, for instance, white wine is served with both fish and meat. This is no doubt because the region produces very little red wine and because Alsatian whites go so well with pork and pork sausages that

The French meal invariably includes cheese. The French are among the world's highest consumers of cheese, but the cheese is generally eaten with wine. A waiter at Le Grand Vefour restaurant in Paris is shown here serving cheese from a cart. © OWEN FRANKEN/CORBIS.

the famous Alsatian *Choucroute* (sauerkraut with an assortment of salted and smoked pork products) is *never* served with red wine but with an Alsatian white wine (or beer). The full-bodied whites of Burgundy can also be served with poultry and go surprisingly well with *pâtés* of all kinds. In the Jura the distinctive sherry-flavored "yellow wine" (*vin jaune*) may be served with poultry or fish, especially when cooked with cream and morel mushrooms from the nearby mountains. In Bordeaux, oysters on the half shell are eaten with grilled link sausages, a delightful combination with which the wine of choice is a white Graves. Conversely, it is also in Bordeaux that one encounters the unusual practice of serving red wine with fish, most specifically lamprey eel, which is cooked in a red wine sauce.

### White before red

This is true so long as the wine is dry, the case for most of the white wine produced in France. Sweet white wines or champagne, on the other hand, can be served at the end of the meal. Admittedly, this practice is dying out and, these days, one is more likely to be served a glass of sweet *sauternes* with a slice of *foie gras* as a starter than with dessert, and champagne is a favorite *apéritif* throughout the country.

### Serve wines in ascending order (the best wine last)

Exponents of this idea argue that if the best wine is served first, all that follow will disappoint. Those who question this approach point out that cheese and dessert come in last place, hence the best wine would always be served with one of them. The problem is an obvious one: great wines are not always at their best with cheese (dessert wines are rarely served these days). Though certain wines can be exquisite with specific cheeses (Alsatian Riesling with Munster, red Burgundy with a pungent *époisses*) certain subtleties in very fine wines can be lost if the cheese they are served with is too pungent. One solution is to follow a complex, mature wine that was served with the main dish with a young, full-bodied wine carefully chosen to enhance the taste of the cheeses. The wine in question is so different from the preceding one that the two cannot really be compared, leaving the impression of progressing from a delicate, suave taste to a "stronger" one.

### Drink wines of a region with foods from that region

Although this rule applies marvelously well to the foods and wines of the lesser-known regions, oddly enough the great wine-producing regions—Bordeaux, Burgundy, and Champagne—are not associated with a wide range of regional specialties. Though Burgundy is rich in natural resources, notably beef, too often *any* dish with a red wine sauce is (mistakenly) considered to be *bourguignon*. Few French people can name even one dish that is specifically associated with either Bordeaux or Champagne. This is not to say that they do not exist; they are simply

unknown to the public outside the region. Bordeaux, for example, claims to produce some of the finest lamb in all of France (*agneau de Pauillac*) and every spring the *Bordelais* delight in grilling shad, fished in the Gironde estuary. Dishes one might encounter when traveling in Champagne often have no specific links to culinary traditions: add a splash of Champagne to virtually any dish and, *voilà!* you've made it *champenois!* The true specialties from that region are simple farmhouse food—poached salt pork and cabbage, tripe sausage, dandelion salad—hardly what one might accompany with a glass of vintage bubbly.

### Reds at room temperature, whites chilled

This is perhaps one of the most misunderstood and frequently challenged practices in France. What exactly is “room temperature”? Essentially this means that wines should not appear to be cold when served. Too often, “room temperature” is interpreted to mean “warm,” a terrible blunder. Though most of the best reds are still served “at room temperature” (60–63°F/16–17°C for Burgundies and 64–66°F/18–19°C for Bordeaux) there is a growing tendency to serve young, fruity reds at “cellar temperature,” cool but not cold (55°F/12°C). This is specifically the case of *Beaujolais* and the light reds from the Loire Valley.

Though white wines are generally brought to the table in an ice bucket, wine stewards in better restaurants often advise their clients to chill fine, full-bodied whites like those from Burgundy just long enough to bring them slightly below “cellar temperature” and feel cool to the tongue (about 48–50°F/9–10°C). Only young, very dry white wines, light rosés, or sparkling wines should be drunk truly cold.

One of the most dramatic exceptions to this rule concerns the famous “yellow wine” from the Jura. This is the only white wine made in France that is served at room temperature.

### Wine and Pleasure

Ideally, a wine should enhance the food it is served with and vice versa. This is why wine is rarely served with salads unless they are made without vinegar because vinegar ruins the taste of wine. Most people are familiar with a few “perfect marriages” (oysters with *muscadet*, lamb with Bordeaux, Sauternes with *foie gras*) though several recent books have encouraged the exploration of more daring combinations like white wines with goat cheeses and pâtés, or light reds with certain fish like fresh grilled tuna or sardines. Nonetheless, the French have conservative tastes generally speaking, and are more likely to respect the rules given above than to break them (regional practices aside). Drinking wine is part of life, not an intellectual exercise, and what count most of all are the pleasures of the table—many French people could not imagine even a simple meal without a glass of wine.

Although wine, whatever its origin, is indispensable to a French meal, one should never conclude that the French are wine “experts.” Most people are familiar with only a limited array of wines and do not anguish over making choices. On festive occasions, however, wine takes on central importance and much time might be spent selecting and orchestrating the serving of several wines. Foreign wines are still an oddity; indeed, those who live in wine-producing regions are often perfectly content to drink *only* wines from their area.

The French are more interested in enjoying their wines than in analyzing them. This is not to say that they do not pay attention when selecting wine, or that they are not attentive when wine is served. But they are more concerned with serving wines to enhance the pleasure of a meal than in anything else. This customarily implies personal discretion and moderation: getting drunk is considered antisocial and severely frowned upon.

### FRENCH AND BRITISH COOKING COMPARED

England and France are two countries which, in world perspective, are actually rather similar. Their pattern of long-term development differs subtly in detail but in broad terms is equally similar, and their cultures and cuisines have been in reciprocal contact ever since the Middle Ages. Moreover, the alimentary raw materials available were broadly the same though not identical. How, then, did their strikingly different culinary cultures take shape?

Caricature is a serious danger in this field. What people eat is universally a potent ingredient of national and social stereotyping. That applies both to the formation of people's “we-images” of their own group and of their “they-images” of outsider groups. Food has long played a prominent part in the sense of national identity of both the English and the French, and it is very risky to accept their reciprocal stereotypes of each other's cuisine at face value. At the very least, one must not fall into the trap of comparing, say, the food of Paul Bocuse with that served at some British transport café, or French professional cuisine with English domestic cookery. Yet, the conclusion is that such common stereotypes as the rotund and rubicund John Bull sitting at a table of roast beef, or the lank and bony French cook smelling of garlic and spearing a frog leg with a fork really do have a kernel of truth in them, particularly in relation to underlying attitudes.

Still-life photographic study of the flavors of France. © MATTHIAS KULKA/CORBIS.

This investigation took as its baseline the late Middle Ages, reviewing the published documents and drawing upon the work of specialists, notably Stouff's outstanding monograph (1970) on late medieval Provence. The picture that emerges from such studies can be briefly summarized. First, the national differences in cuisine that we take for granted were as yet very little developed in medieval Europe. Members of the same estate of society ate in strikingly similar fashion throughout Western Europe. Before Columbus, many of the vegetables now seen as typically Mediterranean were unknown, so that, for example, the humble cabbage was as prominent an item in Provence as in Northumberland. Second, however, the differences between the estates were quite marked, though quantitative differences in consumption were possibly more striking than differences in quality (with an exception registered for a very small elite in really major courts). Stouff depicted graphically the increase in sheer quantity of food consumed as one progressed up the social ranks. Before the Black Death, this was especially marked in the case of meat, though subsequently meat was relatively abundant for the lower ranks, too. The famous gargantuan banquets thrown by kings and nobles to mark particular occasions were no-

table for their vast scale rather than the subtlety of the cooking; their motivation and social function resembled that of the potlatch among the Kwakiutl Indians. Only in the greatest princely courts, and even there probably only for the more special occasions, was the famous courtly cuisine with its elaborate mixtures and proliferation of spices to be found. The recipes found in the manuscripts, whether from France, Italy, or England, are strikingly similar.

Although the evidence from the Middle Ages is too sparse to be conclusive, the best guess from the similarity between surviving manuscripts from different places and periods is that the pace of change in matters culinary was then very slow in all strata of society. From the time of the Renaissance onward, however, the pace of change perceptibly quickens in these as in so many other aspects of everyday life (cf. Elias, 2000), at first among the secular upper classes and then very gradually among lower strata, too. We must be careful: the history of eating is a prime instance of what Elias has called "the polyphony of history." Marc Bloch contended that only in the nineteenth century was it possible to see "the beginning of a trend towards greater uniformity in food—speaking in very relative terms—from the top to the bottom of the social ladder (1970, p. 232)." Until then, the food and the cookery of the peasants in the countryside seem to have changed only extremely slowly over the centuries. It was something to be studied in the perspective of the *longue durée*. From the advent of the printed book, however, it is possible to trace a gradually accelerating pattern of change in the cookery of the upper and upper middle classes. If changes in technique and fashion never quite attain the pace of *histoire événementielle*—although the gastronomic myth-makers delight in representing the invention of new dishes as unique creations of great men on unique occasions (see Mennell, 1985, Chapter 10)—it could fairly be portrayed as *histoire des conjonctures*.

The first elaborate cuisine representing a definite change from the medieval traditions is to be found in the secular and religious courts of Renaissance Italy, but the leadership of Europe in culinary as in so many other facets of culture soon passed to France. Very detailed work by Jean-Louis Flandrin and his associates in Paris may be interpreted to show that French leadership goes back further, but from the appearance of La Varenne's famous book *Le Cuisinier François* in 1651, it does not require in-depth research to see that something recognizable to later eyes as a distinctively French style of cuisine has emerged. From then on, the cookery books are more numerous, and not only can advances in cookery techniques be seen, but it is quite clear that contemporaries were conscious of the rapid pace of change and of the importance of food as an aspect of fashion in courtly circles. By the 1740s, the first gastronomic controversies were being fought out in Paris between minor courtiers (Mennell, 1981). Although by then cookery books were being directed specifically at the bourgeoisie, and some

differentiation between courtly haute cuisine and domestic cookery was being codified, the models still clearly stemmed from courtly circles. One of the important consequences of this was that the spirit of thrift and economizing in the kitchen, which was very marked from an early date in England, was much less in evidence even in French cookery books, and something of the courtly functions of luxurious display heedless of the cost (cf. Elias, 1983) lived on until the present day in the French kitchen.

In England, the cookery books from the late sixteenth century onward depict a more rustic, “country housewife” style of cookery. They were still directed at readers among the nobility and gentry—this is not the food of the peasants—but they reflect their readers’ greater continuing involvement in country life and pursuits than was the case among their French counterparts. There was for a time a line of English courtly cookery books too, but that tradition lost its vitality in England after the Civil Wars of the mid-seventeenth century, and from the early eighteenth century it is eclipsed by the resurgence of the “country housewife” style of book, written mainly by women, unlike those of the French and courtly traditions. The spirit of thrift and economy, often linked with an overt hostility to French extravagance, is strongly expressed.

This is a very compressed summary of only part of the evidence for differences in culinary culture between England and France. To counteract the necessary oversimplification, it must be emphasized that when speaking of “English cookery” and “French cookery,” we are not dealing with two entirely separate things. French cookery had an early and continuing influence on English cookery, particularly through English cooks having worked in France and French cooks working for the very wealthiest English families. Yet there is a valid contrast. The food of the English gentry and prosperous farmers, depicted in the English cookery books, enjoyed a prestige of its own to which there was no equivalent at that date in France. From the technical point of view, there are also clear differences. The French developed a “cuisine of impregnation,” replacing the antique “cuisine of mixtures.” The use of *cullis* (the English translation of *coulis*) as a *fonds* and the proliferation of sauces—a process carried still further in France in the nineteenth century—was precisely not the foundation of English cookery. In England, continuities from the past were much more in evidence. The old pies and joints of meat remained the center of the English meal, whereas in France the focus of attention shifted to the ever-increasing variety of delicate little “made dishes.”

What explanations can be offered for the rather different courses of development observed in the taste in food of the two countries?

One explanation has been so often repeated that it has the force of conventional wisdom. It is that meat (and

other raw materials) were so abundant and of such superior quality in England that it was not necessary to cook them with great skill, disguise their flavor, or eke them out in made dishes. This explanation is implausible. For one thing, the superiority and abundance of English raw materials is highly questionable. For another, this popular explanation rests on the implicit proposition that all human beings prefer the “natural” taste of foods, transformed as little as possible by the culinary arts, which are thus seen as little more than a forced adaptation to circumstance. There is no serious evidence for this proposition.

On the contrary, three more explicitly social strands of explanation bear closer examination. These are, first, the possible influence of Puritanism, or other religious differences between England and France; second, the role and influence of the court society, and, more generally, differences in the distribution of power and social stratification; and, third, the differing relationship between town and country on the two sides of the Channel.

The influence of religion on eating is certainly very strong and familiar in many of the world’s cultures. But the contention, advanced by such popular writers as Philippa Pullar (1970), that Puritanism blighted the English kitchen needs to be treated with some skepticism. For one thing, it is not clear that the English Puritans of the mid-seventeenth century were at all the general killjoys of later stereotype; they certainly do not have much to say against enjoying one’s food. Later, perhaps, as Dissenters, their outlook narrowed, but by then they were not in the prominent positions in society from which they might once have commanded taste-setting power. Moreover, it is often overlooked that, besides the sizeable Huguenot community, seventeenth-century France also saw an influential Jansenist current within Catholicism that has long been seen to have similarities to the Calvinist predestinarian kind of Protestantism. Yet no one has ever suggested that Jansenism permanently damaged French taste buds.

As for the royal and princely courts, their direct influence on the authors of French cookery books is plain to see. In the light particularly of Norbert Elias’s account of the place of luxury and display in French court society (1978), it is highly likely that competition between courtiers would be acted out through their kitchens and their tables as in many other aspects of culture. An essential link in the argument is that the French nobility, having emerged on the losing side from a series of struggles with the king, became deracinated and defunctionalized—deprived of their roots in a rural way of life, deprived in particular of their relatively independent power bases and governmental functions in the provinces. This did not happen to the same extent in England. The power shifts that were the outcome of the Civil Wars, the Glorious Revolution of 1688, and the Hanoverian succession in 1714 nipped in the bud the growth of an absolutist monarchy and court society on the French

model. The royal court in eighteenth-century England was more *primus inter pares*; noble houses and the gentry retained a relatively independent power and governmental function in the provinces; and the pressures toward competition through virtuosity in consumption were relatively less intense.

That connects with a third consideration. The relationship between town and country in England was rather different from that in France. It was not that England was a more rural country than France. Quite the contrary. London in the eighteenth century was absolutely bigger than Paris, and its population relatively still larger as a proportion of the nation as a whole. It is estimated that as many as one in six people in that period spent some part of their lives in London. Nevertheless, the prestige of the country way of life remained much higher in England than it did in France, and London and country society remained more closely interlocked than in France. A larger proportion of English noblemen and gentlemen spent a larger proportion of the year living on their country estates and largely eating the seasonal products of their lands than was the case in France. Rustication from court was dread punishment for a French courtier. Besides, it should not be forgotten that in a preindustrial economy the range of available foods was generally more limited in the country than in the markets of major cities. The very diversity of the products to be found in the principal markets of great cities is a prerequisite for the creation of a great diversity of made dishes. Haute cuisine is a characteristic of urban life.

### **Convergences: The Nineteenth and Twentieth Centuries**

After the Napoleonic Wars, the divergence between English and French cuisines appeared to widen. What was actually happening was something rather more complicated. Certainly, French professional cuisine, founded in the aristocratic kitchens of the ancien régime, was raised to new heights through competition between the restaurants of nineteenth-century Paris. And there is a good deal of evidence that, especially in the latter half of the century, the rather fine English country cooking tradition declined and became coarsened. What appears to have happened was that French culinary hegemony in the higher circles of English society became far more firmly established than in the eighteenth century, when only a few of the greatest grandees had employed French chefs. French culinary colonialism now extended further down into the highest reaches of the middle class. Besides, the sheer number of families involved in London "Society" was growing very rapidly (Davidoff, 1973), and the intense competition created by this social inflation mimicked in some degree the competitive display found among French courtiers a century earlier.

It was not, however, likely that these conditions would favor the emergence of a separate and distinctive English haute cuisine. Something like the "dependency

theory" of "world-systems" theory applies to culinary colonialism as well as to colonialism proper. French cookery having already reached great heights, its techniques, recipes, rules, and vocabulary were there to be adopted by the colonized, just as about the same time the advanced state of many English sports led to the adoption of the games and their English vocabulary in many parts of the world.

The coarsening of the English "country housewife" tradition of cookery in the nineteenth century may have been due not just to the defection of the social model-setting circles to French cuisine but also, lower down the social scale, to the disruptive effects of very rapid urbanization and population growth on the transmission of traditional knowledge from mother to daughter. Urbanization took place in England far earlier and far more rapidly than in France. By the time the corresponding movement to the towns took place in France, largely during the twentieth century, the popular press and other mass media may to some extent have provided alternative channels for the maintenance of traditional knowledge.

That is to some extent speculative and requires deeper investigation. What becomes quite clear, however, is that by the 1960s, forces leading to convergence between the culinary cultures of France and England were dominant over the forces of divergence. That was to be seen quite clearly in the further diffusion of French influence down the English social scale through cookery columns in women's magazines and cookery programs on television. But far more important was the enormous growth of the food processing industry and its impact on the domestic kitchen in both countries and indeed throughout the developed world. That, and the growth of the fast-food industry, have become very powerful agents for the internationalization of food, and that has involved contrary yet interlinked trends both to standardization and to the greater diversity of styles in an increasingly cosmopolitan culinary culture. This applies not just to the actual dishes that come out of domestic and commercial kitchens, but also—in the richer countries—to social contrasts in eating. Both have been marked, in Elias's phrase, by "diminishing contrasts and increasing varieties."

In summary, France and England, two similar neighboring countries that had been in continuous contact with each other since the Middle Ages, nevertheless developed contrasting culinary cultures. The explanation for why that happened should not be sought not in any "innate" differences in the "taste" of English and French people, nor to any great extent in their natural endowments of alimentary raw materials, nor yet in religious differences. An answer lies rather in the divergence between their social structures from about the seventeenth century onward. In particular, competitive display and virtuoso consumption played a more compelling part in the absolutist monarchy that developed in France under Louis XIV and up to the Revolution than it did among the gen-

try and aristocracy in England after the defeat of the king in the Civil Wars in the mid-seventeenth century. Linked to these differences in stratification was a different relationship between the city and the country. French haute cuisine had its origins in courtly cookery, and courts are urban institutions. In contrast, the greater prestige of the country way of life in England is reflected in its cookery.

**FRENCH FRIES.** In the United States, potatoes cut into long strips and fried in deep fat have been known as french fried potatoes, then french fries, and now just "fries."

French fried potatoes are a favorite food in countries around the world. What makes them so popular? Perhaps it is the flavor of the fat, or the salt—or both—that leads us to purchase the potatoes often. French fries do not require eating utensils in informal situations, which makes them easy to eat and to carry away from the point of purchase. The many restaurants selling french fries frequently combine servings of fries with another food, for example, fried fish or hamburgers. Also, these restaurants advertise widely, so we are tempted to buy french fried potatoes repeatedly.

#### Origin

There is disagreement as to the origin of this method of cooking potatoes. Because the term "French" is used in the name, many people give cooks in France credit for having first prepared french fries. A French writer of the nineteenth century who went by the name of Curnonsky (his real name was Maurice Edmond Sailland) said that if there were regional Parisian cooking, its greatest contribution to gastronomy would be *pommes frites* (French fried potatoes). Others have suggested that "French" refers to the way in which the potatoes are cut, into lengthwise strips, as with frenched green beans.

Legend has it that President Thomas Jefferson introduced the deep-fried potatoes at a state dinner in 1802 upon his return to the United States from a trip to France. There seems to be no record of them in the United States for about sixty years. Some restaurants were selling them by the 1860s, but this form of potatoes was not popular here until the 1920s when World War I veterans returned from Europe. Drive-in restaurants, opened in the 1930s and 1940s, sold french fries. Since they did not require a utensil, they were easy to eat while driving.

A British food history book states that "chipped" potatoes were introduced into Britain from France about 1870. The term "chips" is used to designate fries in Britain, while potato crisps is the British name for what are known as chips in North America. The British "chipped" potatoes were paired with fried fish and sold in shops instead of the sliced bread or baked potatoes that had accompanied fried fish since about 1850.

#### Preparation

In French cookbooks, one finds recipes for potatoes cut into many shapes before frying. For example: *pommes frites allumettes* (also called *julienne de pommes de terre*), which are matchstick-shaped; *pommes frites paille*, cut into thin straws; and *pommes gaufrettes*, which are waffle-shaped potatoes. It is not usual to find a recipe for plain *pommes frites*. *Pommes frites pont-neuf*, first sold in a Parisian restaurant on the Pont Neuf, may be the closest to our traditional shape for fries.

Recipes for soufflé potatoes are found often in French cookbooks. Soufflé potatoes were first made in 1837, when a dinner being prepared for King Louis Philippe and Queen Amelie was held up by the late arrival

The curse of nutritionists, the enemy of sustainable agriculture, the standby of the teenage diet, French fries are not only loaded with fat, but are also the subject of heated debate and a symbol of food globalization. © ROBERT YOUNG PELTON/CORBIS.

of the guests of honor. The chef took the potatoes off the heat before they were quite done, then put them back into hot fat just before serving. The potatoes puffed and were a great success at the dinner. French fries are said to be of best quality when they, too, are partially cooked at a lower temperature, then finished in fat that has been heated to a higher temperature; that has become the traditional way of preparing them. Some American cooks were doing this at home about 1950. American food writer Pam Anderson has developed what she calls a new way for home cooks to do fries, using less oil and raising the temperature of the oil toward the end of the cooking period, rather than removing the potatoes from the fat, then adding them back later. The method still depends on the two different temperatures for a good product.

In the United States, Russet Burbank potatoes are the variety used most for frozen fries. This variety does not grow well in other countries, so about half a million metric tons of frozen fries are exported annually. The greatest market for these is Asia, with the Japanese being the largest consumers. Other potato varieties, especially Bintje, are used fresh for fries in the Netherlands and France, and by some sellers on the East Coast of the United States.

One potato expert says that the best french fries are made in the Netherlands, where they are found on almost every street corner in Amsterdam. There, the fries are served with lots of ketchup, mayonnaise, and mustard on top. Others think the Belgians have the best fries, and

there are shops in New York City selling Belgian-style fries. The Belgians are known to eat *pommes frites* more often than the Americans. The correct term for potatoes is *pommes de terre*, "earth apples," but no one seems to be confused by *pommes frites*. Belgians might eat them every day, both with meals and as snacks. Along with coffee, *pommes frites* are known as Belgian staples. The potatoes are usually served with mayonnaise, tartar sauce, Russian dressing, or béarnaise sauce, and may be accompanied by pickles or pickled onions. In Paris, the best *pommes frites* are said to be made by Algerians, Turks, and Greeks, rather than by French cooks. In each of these countries fresh potatoes are used rather than frozen ones. Americans tend to like fries with tomato ketchup accompanying them, and, in the northernmost parts of the United

A Belgian writer says that *frites* shacks, small wooden shops selling fries along the sidewalks, have all but disappeared in Belgium. In the 1940s in the United States and Canada, there were trailers selling freshly cooked fries parked along the streets of small towns or at beaches.

States and in Canada, vinegar is the choice of topping, a practice probably adopted from the British.

The fat in which the potatoes are fried can make a big difference in flavor of the finished product. McDonald's fries used to be cooked in a mixture of vegetable oil and beef tallow, which gave them a unique flavor. This practice ceased when enough consumers complained about the saturated fat, and so all vegetable fat has been used, and no beef tallow, since 1990. The flavor was different, though, so natural beef flavor was added to the frozen fries, much to the outrage of vegetarians, who expected there to be no animal product in the potatoes. A Belgian recipe for *pommes frites* calls for beef kidney suet, which gives them a unique flavor.

A Dutch-Egyptian factory near Cairo uses palm oil for its fries. A *New York Times* food writer fries the potatoes in a mixture of peanut oil and duck fat with bacon added. Another suggestion is to use horse fat, which is difficult to obtain in the United States. Burger King coats the potatoes with a mixture of potato starch and rice flour, then uses liquid smoke for flavor, but does not tell consumers what kind of fat is used.

### French Fries as an American Icon Food

In America, frozen french fries were sold at R. H. Macy in New York City in 1946. Maxon Food Systems of Long Island City introduced the fries, but the company failed. Idaho potato processor J. R. Simplot had chemists develop frozen french fries for his company in 1953. These did not catch on because the potatoes tasted best when reheated in hot fat and home cooks did not want to bother doing that for a convenience food. Simplot decided to aim at restaurant owners who would be interested in saving labor in preparing potatoes for frying.

In about 1966, McDonald's restaurants began selling Simplot's frozen french fries. The potato processor had a new factory built just to prepare the fries for McDonald's. Customers did not object to the frozen product, and the reduced labor cost meant that french fries became a very profitable menu item. By 1995, Simplot had produced two billion pounds of french fries and other frozen potato products in the northwestern United States and in China.

Residents of the Southeast United States eat more french fries than those of the rest of the country. The Midwest is next, with the West and the Northeast following in that order.

Monitoring the sugar content versus starch content of potatoes is important in getting top-quality fries. If there is too much sugar, the potatoes will brown too fast. Companies may add some sugar to the fries in the fall, and leach out sugar in the spring, in order to get uniform color and taste throughout the year. Storage temperatures will affect sugar content of the potatoes.

In 1960, Americans consumed eighty-one pounds of fresh potatoes per capita and approximately four pounds of frozen french fries. By 1971, the consumption of processed potatoes was greater than that of fresh potatoes. Frozen potatoes accounted for most of the processed potatoes. In 2001 the consumption was forty-nine pounds of fresh potatoes and over thirty-one pounds of frozen french fries. The thirty pounds is equal to about four servings of fries a week. About 67 percent of the fries are bought at fast-food restaurants, with other restaurants accounting for 13 percent of the market share. Americans aged sixty and above eat fewer fries than younger persons.

There are now two other American frozen potato processors larger than Simplot: Lamb Weston, part of ConAgra, and Ore-Ida, owned by Heinz Frozen Food. Both of these companies are located in the Northwest. Lamb Weston processes fries for McDonald's and makes more than 130 different types of fries, some of which are sold in school lunch programs. In 2002, Ore-Ida stimulated sales of frozen french fries by introducing Funky Kool Blue Fries (not made from blue varieties of potatoes, but artificially colored a brilliant blue), chocolate-flavored (and colored) fries, and cinnamon sugar fries.

Frozen french fries have been a profitable item for fast-food companies. In 2001, it was possible to buy the potatoes for about 30 cents a pound and sell french fries for around \$6.00 a pound. Unfortunately, farmers get very little of the profits. Increasingly, big corporations own the farms, while the farmers who have been driven from the land are hired to manage the farms for the corporations.

**FROZEN FOODS.** In the early twenty-first century, frozen foods are an important component of meals prepared and served in both homes and restaurants. They have expanded the kind and quality of meals served and continue to influence food preparations and consumption in this country. The variety of frozen foods in the market reflects the wide use of frozen foods in households. These include ethnic, vegetarian, fast foods, imported gourmet, dietary, and many others.

Early use of freezing occurred in parts of the world, such as Canada, where temperatures in winter drop below freezing for significant periods of time. When hunters brought game animals home in winter, it was possible to freeze the catch by using the outdoor environment as the freezer. It was also convenient on farms where butchering was done. These meats were frozen and used before temperatures moderated. Experiences like this demonstrated the advantages of freezing. Because the storage time was dependent on the weather, this procedure had limitations.

The advantages of freezing as a method of preservation prompted researchers to develop freezing technology. In 1842, a patent for freezing foods by immersion in a brine of ice and salt was issued to Henry Benjamin in Britain. Fish was first frozen in the United States in 1865, and in 1917, Clarence Birdseye began word on freezing foods for retail trade. The use of dif-

ferent refrigerants was one of the early needs examined. The possibility of freons as refrigerants was well received for industrial and consumer applications and led to their early incorporation into household freezers. These early models offered were large in size and were designed to be used for the game and butchering needs of farm families at that time. But soon after their introduction, it was obvious that they were extensively used to store fruits and vegetables, an attractive application for farm households who were growing their own produce. These early models were great successes, and they launched the freezing preservation of fruits and vegetables in this country.

The possibility of freezing preservation of fruits and vegetables became an important interest in the United States, catching the attention of many city apartment dwellers and suburban families who lived in small houses. Unable to accommodate the large-size freezers that appliance manufactures were selling to farm families, these householders teamed up with their neighbors to develop community freezers, where families could rent freezer space in a large freezer-locker rental operation. Although this solved the problem, it was less than convenient.

Questions were raised about the effect of freezing meats, fruits, and vegetables on the quality of the thawed

## TV DINNER

In 1954 C. A. Swanson & Sons introduced TV dinners to consumers in the United States. Gerald Thomas, an executive at Swanson, conceived the idea after the company unexpectedly found itself with 520,000 pounds of unsold Thanksgiving Day turkeys (information available at any website on popular culture of the 1950s). The turkeys were being stored in refrigerated railroad cars moving coast to coast across the country because there was not enough storage space in the company's warehouses. Thomas also conceived of the idea of using aluminum trays with three separate compartments. Based on his experiences in World War II, when soldiers ate from a tray, commonly known as "mess gear," he wanted to solve the problem of different foods running together in their serving tray. He observed the lightweight metal trays then being utilized by the airline food industry to heat meals and adopted them for use with the TV dinner.

The TV dinner concept was not met with immediate approval or enthusiasm at Swanson, though, where two more traditional-thinking brothers owned and operated the company. It was not until the older brother, who opposed the idea, went on vacation that Thomas's idea became a reality. The first dinner contained turkey, corn bread stuffing, gravy, sweet potatoes, and buttered peas. Its packaging was designed to look like a TV. Because most consumers did not own freezers in 1954, the dinners were usually consumed on the day they were purchased.

The market for TV dinners, or "frozen food dinners or entrées" (as they have come to be described almost exclusively by the frozen food industry since the 1960s), has continued to expand over the past five decades, reflecting the values and concerns of a larger American society. The initial production order by Swanson was for five thousand dinners, at a cost of 98 cents to consumers. Within a year, Swanson sold more than ten million turkey TV dinners. To ensure successful sales of the TV dinner, Swanson created an ad campaign featuring Sue Swanson, who "re-assured housewives they needn't feel guilty

about not cooking homemade meals for their families." During the 1960s the sale of frozen food entrées rose dramatically after it became well publicized that the first American astronauts to land on the moon ate prepared meals while in space. In the 1950s and 1960s these entrées featured mostly comfort foods, similar to the homemade dinners that "Mom" would make, such as meatloaf or fried chicken combined with mashed potatoes.

The microwave oven was then invented in the 1960s, and it became a standard feature in most American homes by the 1980s. This development further increased the convenience and attractiveness of TV dinners to consumers. The 1980s witnessed a rise in the production of ethnic, low-calorie, and budget entrées, whereas the 1990s saw an increase in the production of gourmet entrées, "kid cuisine," and "hearty portions." The new millennium has so far indicated increasing growth in the production of frozen food entrées that are either healthy or "wholesome."

The frozen dinner is currently the largest category within the frozen food market; it currently accounts for over \$5 billion worth of supermarket sales annually. One of the ten most popular dinners served in American homes is now a TV dinner, and nearly half of all Americans purchase frozen entrées. Those individuals most likely to consume TV dinners are "blue-collar families, older couples, and retired singles," whereas those least likely to consume TV dinners are either more wealthy families living in the suburbs or poorer people living in the country (see *American Demographics* for further information). In addition, frozen dinners are being delivered increasingly across the country to individuals who are homebound because of poor health or functional impairment. Survey findings reported by the Frozen Food Institute in 2002 reveal that certain frozen foods are among the top three items that Americans would not want to live without.

*Julie Locher*

product, including its nutrient retention. The USDA and land grant universities responded to this concern with research studies to assess the impact of freezing on nutrients in fruits, vegetables, and meat, which are summarized by Karmas and Harris. The results of this work showed the nutritional advantages of frozen foods and gave recommendations for freezing methods aimed at retaining maximum quality and nutritional value.

During World War II, homemakers began to join the U.S. workforce in large numbers and appreciated the timesaving advantages of frozen food. The appliance and food industries noted the acceptance by consumers of both freezing preservation of foods and the small freezer sections in household refrigerators. Early models of refrigerators did not offer separate compressor units for the freezer section. As a result, these appliances provided only

limited freezing capacity and ability to freeze. The development of appliances with freezing sections that had separate compressors that allowed the freezing section to successfully hold frozen foods in the frozen condition had a major impact on the consumer's ability to store food. The food industry has also responded to the abilities of the new refrigerator models to hold frozen food by introducing frozen foods such as entrees, vegetable, breads, fruits, desserts, juices, snack foods, and ice cream. The refrigerator and freezer combination appliance fits into small spaces and is especially appreciated by those living in apartments and small homes. In the early twenty-first century, few refrigerators do not include a freezer on a separate compressor.

In microwave heating, foods are placed in an electromagnetic field when they are positioned in the oven cavity and the microwave energy is turned on. Heat is generated by molecular friction among the free water molecules in the food load. Since a frozen food has a very small amount of unfrozen water that attracts the microwave energy first, the heat is generated in a small part of the food load and is rapidly absorbed by the frozen part. In frozen foods, a large part of the water is in the form of ice. While water readily absorbs microwaves, ice does not. Some of the water in frozen foods does not freeze; this may be due to the salt content. The unfrozen water absorbs microwaves quickly in the microwave appliance. As a consequence, the use of microwaves to thaw and cook food may result in "runaway heating," a situation in which the unfrozen water containing salts is boiling while next to it, areas of ice exist. To prevent this, a defrost program is recommended; this feature exposes the food load to microwave energy for a short time, then turns microwaves off for a slightly longer time, allowing the heat to be conducted to the ice. This cycle is repeated until thawing is completed and does not usually produce runaway heating.

## FRUIT.

*This entry includes three subentries:*

Citrus Fruit

Temperate Fruit

Tropical and Subtropical Fruit

### CITRUS FRUIT

Citrus fruits are native to southeastern Asia and are among the oldest fruit crops to be domesticated by humans. They are widely grown in all suitable subtropical and tropical climates and are consumed worldwide. The most important of the citrus fruits commonly eaten include sweet oranges, mandarins, lemons, limes, grapefruits, and pummelos. These are eaten fresh, juiced, and in processed products. Citrus fruits have well-documented nutritional and health benefits as well as industrial uses. Their beauty and utility were well described by Georges Gallesio in 1811:

Of all the plants spread by nature upon the surface of the globe, there are none more beautiful than those we know under the names of citron, lemon, and orange trees which botanists have included under the technical and generic name *Citrus*. These charming trees are both useful and ornamental. No others equal them in beauty of leaf, delightful odor of flowers, or splendor and taste of fruit. No other plant supplies delicious confection, agreeable seasoning, perfume, essences, syrups, and the valuable aides so useful to colorers. In a word, these trees charm the eye, satisfy the smell, gratify the taste, serving both luxury and art and presenting to astonished man a union of all delights. These brilliant qualities have made the citrus a favorite in all countries.

### Botany

Citrus fruits constitute several species of the genus *Citrus* of the subfamily Aurantiodeae of the plant family Rutaceae. The Aurantiodeae has a total of thirty-three mostly subtropical and tropical genera, a few of which have economic importance. Most genera originated in Southeast Asia: the Malaysian and Indonesian Archipelagos, the Indochinese Peninsula, India, and China. A few genera originated in Australia or Africa.

The citrus fruits proper are characterized by their distinctive fruit, the hesperidium, which is a berry with the internal fleshy parts divided into segments (typically 10 to 16) and surrounded by a separable skin. The name is derived from classical mythology, referring to the "golden apples" grown in the garden of the Hesperides (the daughters of Hesperus, the evening star), located in

the far west, in Paradise. When grown naturally, citrus plants are generally small to large trees, with glossy alternate leaves having oil glands. The attractive and fragrant flowers have an annular disk and generally bloom in the early spring.

The genus *Citrus* is divided into two subgenera, *Citrus* and *Papeda*. The former contains “edible” citrus fruits (including some less than palatable varieties), while the latter consists of the papedas. These are a distinctive group, the fruits of which have high concentrations of droplets of acrid oil in the pulp vesicles, rendering them inedible due to the bitter, unpleasant flavor. The leaves are also distinctive as compared to those of the subgenus *Citrus*, having large, prominent petioles. The leaves of one species, *Citrus hystrix*, are used as a condiment in Southeast Asian cooking.

The taxonomy of *Citrus*, as a genus, is unclear. So, for that matter, is the taxonomy of the other thirty-two genera in the subfamily. Different authorities have recognized anywhere from 3 to 170 species of *Citrus*. Obviously, this large a difference is due to more than mere hair-splitting. The most commonly used systems, that of W. T. Swingle (see Reuther, Webber, and Batchelor, pp. 190–430) or its modifications, recognize about sixteen species.

Most of the difficulties in *Citrus* taxonomy arise due to the free hybridization that can occur between different varieties and even between different species of *Citrus*. In fact, many of the other Aurantiodeae genera are capable of free hybridization with *Citrus*. The result is that many types of citrus arose from these hybridization events at some time in the past. A strict interpretation of the “species” concept would result in fewer types being awarded species rank, whereas a looser interpretation would result in a higher number of species. This problem is compounded by the numerous controlled hybridizations and selections made by humans with the goal of producing a more desirable fruit.

Currently, the generally accepted concept is that there are three primordial or fundamental *Citrus* species: *Citrus medica* (citrons), *Citrus maxima* (pummelos), and *Citrus reticulata* (mandarins). All other types of citrus currently existing arose from single or sequential hybridization events between these species or their offspring. This concept is supported by various types of studies: classical taxonomy, chemotaxonomy, and molecular analysis.

Edible citrus is generally divided into sweet oranges, sour oranges, mandarins, grapefruit, pummelos, lemons, limes, and citrons. Within each of these types there are various subtypes, as well as types that arose from free or controlled hybridization. Depending on the taxonomic system used, these subtypes and hybrids may or may not be accorded species status. Table 1 presents some basic information on these standard types of edible citrus. Some of this information is not strictly accurate in a scientific sense: Oroblanco is actually a hybrid of a pum-

melo and a grapefruit, but it is generally marketed as a grapefruit; Meyer is probably a low-acid natural hybrid of a lemon and a sweet orange, but it is usually marketed as a lemon; Mediterranean Sweet is probably more accurately referred to as a “limetta” rather than a sweet lemon. However, the idea is to present the reader with some general information on fruits that might be encountered and eaten. Some types (low-acid sweet oranges, sour oranges, citrons) are not of much importance commercially, while others (sweet lemons, sweet limes) are important in some regions of the world but not in others.

There are four types of sweet oranges. The navel oranges possess a small, secondary fruit in the stylar end of the main fruit. This is the navel. Since navel oranges were introduced to California from Brazil in 1873, they have assumed a primary importance throughout the world as a sweet orange for fresh consumption. Like the navel oranges, common sweet oranges mature during the winter. Because of the popularity of the navel as a fresh fruit, common oranges are generally grown mostly for processing, although they can be important locally as fresh fruits. Blood oranges have a pigment called anthocyanin in the rind and juice, producing a reddish blush that becomes more pronounced with cooler night temperatures in the fall. The blood oranges have a distinctive taste compared to other sweet oranges. Valencia oranges mature later than the other sweet oranges and are generally harvested in the late spring or summer. Low-acid oranges have about the same levels of sugars as regular sweet oranges, but much lower levels of acid, resulting in a rather bland flavor.

Mandarins are often referred to somewhat incorrectly as tangerines. The word “tangerine” was used in the nineteenth century to designate Mediterranean types of mandarins, and referred to the city of Tangier. This term later became associated with other types of mandarins. Mandarins are of ancient cultivation in China, their probable area of origin, and other parts of Asia. The common mandarins include such important varieties as Ponkan, which is widely grown in Asia under different names. The Satsumas are a distinctive, seedless, early maturing group apparently originating in Japan relatively recently as compared to the common mandarins. The Clementines are another distinctive group that apparently originated in Algeria as recently as the 1890s. There are now many different selections of Satsumas and Clementines. The hybrids of tangelo (crossed with pummelo or grapefruit) and tangor (crossed with sweet orange) are included here as types of mandarins since they are generally thought of by the public as being more like mandarins than the other parent.

Sour oranges are not often eaten as fresh fruit or used for processing. However, the fruit is used to produce marmalade, and the flowers of certain types are used in the production of perfume. The Bergamot, a sour orange hybrid, has a distinctively scented oil that is used in

teas as well as perfume. Sour oranges often make attractive ornamentals.

Pummelos are generally large fruit that originated in more tropical areas than most other types of citrus. They are commonly grown in southeastern Asia, where consumption is the highest. Pummelos are not eaten much outside of that area. The pummelos are a very diverse group, with large variations in size and shape, rind, flesh pigmentation, and acid level.

Grapefruit is another natural hybrid (probably pummelo crossed with sweet orange) arising relatively recently (in the eighteenth century). In the twentieth century, it became widely planted and was used for both fresh fruit and processing. White- and pink-fleshed varieties exist. The pink-fleshed varieties derive their color from the pigment lycopene and require high heat levels for good color development (in contrast to the blood oranges).

Lemons have not been identified as a wild species, and probably arose sometime in the remote past as a cross between a citron and a sour orange (itself probably a hybrid of pummelo and mandarin). Lemons are rather variable and it is sometimes difficult to distinguish between different varieties and types. Low-acid, sweet lemons also

exist. The limettas are similar to and more common than sweet lemons and are often referred to in this manner.

Limes are somewhat similar to lemons in appearance and ancestry, and the distinction between the two groups is not always clear. Like lemons, low-acid, sweet types exist. The acid lemons are generally divided into the large, fruited types (generally seedless) and the small-fruited, “Key” types.

Citrons were probably the oldest citrus fruit to be cultivated in the West, but today they are not widely grown. Citrons are a highly variable group including acid and sweet varieties, but to the general public they often resemble large lemons. Citrons are sometimes used in the production of a candied peel and in Jewish religious ritual. The citrons are aromatic and are occasionally grown as ornamentals.

The kumquats are not, strictly speaking, citrus fruits. They are, however, in the genus *Fortunella*, which is closely related to *Citrus* in the Aurantioideae. Kumquats are distinctive in that they have small fruits with a sweet, edible peel. The trees are small and attractive and they are generally grown as backyard trees rather than commercially. The most important varieties of kumquats are Nagami, Meiwa, and Marumi.

## Natural History and Spread

As well stated in Reuther, Webber, and Batchelor, "The history of the spread of citrus reads like a romance. Even in very early times the beautiful appearance of both tree and fruit attracted the attention of travelers and received mention in their written narratives" (p. 1).

Citrus is native to and has its center of diversity in northeastern India, southern China, the Indochinese peninsula, and nearby archipelagos. A theoretical dividing line (the Tanaka line) runs southeastwardly from the northwest border of India, above Burma, through the Yunnan province of China, to south of the island of Hainan. Citron, lemon, lime, sweet and sour oranges, and pummelo originated south of this line, while mandarins and kumquats originated north of the line. The mandarins apparently developed along a line northeast of the Tanaka line, along the east China coast, through Formosa, and to Japan, while kumquats are found in a line crossing south-central China in an east-west direction.

The cultivation of citrus began in ancient times in these areas. In fact, citrus was one of the earliest crops to be exploited and domesticated by man. Probably cultivation of citrus began independently in several locations within the area of origin and spread throughout the Southeast Asian region, and eventually into the Middle East, Europe, and America.

The oldest mention of citrus fruits known is from China, in the *Yu Kung*, a book of tributes to the Emperor Ta Yu, who lived from about 2205 to 2197 B.C.E. This book mentions the use of various types of citrus as tributes to the emperor. Later writings describe other types of mandarins, sweet oranges, pummelos, and kumquats. The monograph on citriculture written in 1178 C.E. by Han Yen Chih mentions twenty-seven varieties of citrus. The earliest mention of citrus in Indian writings is from about 800 B.C.E. in a collection of devotional texts, the *Vajasaneyi samhita*. This text mentions citrons and lemons. Sweet oranges are not mentioned in Indian writing until about 100 C.E.

The sweet orange probably arose in southern China where both mandarins and pummelos were planted together. From there, it spread through Burma and Assam into India. Much the same route was probably followed by the mandarins. Mandarins also spread into Japan. This probably occurred in the middle of the first millennium C.E., but the first mention of mandarins in Japanese literature dates from the thirteenth century.

Conversely, the citron probably originated in northern India and spread northward into China later. The citron also spread from India westward to Medea (Persia) by the first millennium B.C.E., and then into Palestine and the Near East. It is supposed that it was brought to this area by Alexander the Great. The citron became established in Italy during Roman times. The sweet and sour oranges, lemons, and pummelos followed this route at a later date.

The Arabs were instrumental in introducing most of the citrus types to Europe and northern Africa. The invasion of southern Europe by the Moors introduced citrons, sour oranges, lemons, and pummelos to the Iberian Peninsula, which is still an important area of citriculture. However, the sweet orange was apparently not established in Europe until the fifteenth century C.E. This was probably due to an entirely different route by Portuguese trade with southern Asia. The mandarins were apparently not introduced to Europe until early in the nineteenth century, when they arrived directly from China. Kumquats were introduced from China in the middle of that same century.

Citrus can be, and is, grown in southern Europe. That citrus represented a new and appealing type of fruit and had more exacting climatic requirements created a sort of cult of citrus in the more northern areas of Europe that persists to this day. Since citrus cannot be grown outdoors in such areas as the British Isles, northern France, and Germany, special houses (later known as orangeries) were in use by the fourteenth century for growing oranges and citrons. Some of these structures, which can be considered precursors to modern greenhouses, are still standing. In some cases, the citrus overwintered in the orangeries and were brought outdoors to enjoy the brief and mild summers and to enchant the public.

Citrus was carried to America by the Spanish and Portuguese colonizers beginning in the sixteenth century with the second voyage of Columbus in 1493. From its initial establishment in the Caribbean islands, it spread to the mainland (Mexico) and from there into the southern United States and Latin America. Citrus was introduced into Florida earlier than into California. Citrus was introduced separately into Brazil by the Portuguese, who were also responsible for the introduction of citrus into West Africa. It had apparently been introduced to the African continent earlier by Arab or Indian traders. Citrus was introduced in Australia from Brazil in 1788 by the colonists of the First Fleet.

## The World Citrus Industry

In the New World, as in the Old, wherever citrus was introduced it became a popular fruit. If climatic conditions were appropriate, citrus was planted for commercial and for personal use. It remains the most widely planted fruit, except for grapes, in the world today. Most grape production is for winemaking, so citrus is undoubtedly the most widely planted fruit for direct human consumption in the world.

Citrus is grown throughout the world in the "Citrus Belt" between approximately 40°N and 40°S latitude. Within this belt there are tropical, semitropical, and subtropical climates, and it is possible to grow citrus in all three. Although there is some influence of scion and rootstock in cold susceptibility, frost is the main climatic limitation to citrus production. At the northern and southern margins

The method for protecting lemon and orange trees during the winter along the Lake of Garda in northern Italy. At the beginning of cold weather, the orangerie was shuttered along the front and roofed over with moveable boards. From Johann Christoph Volkamer's *Nürnbergische Hesperides* (Nuremberg, 1708). ROUGHWOOD COLLECTION.

of production (Corsica, Japan, New Zealand), the mildness and shortness of the summers is a secondary constraint. In areas that have a Mediterranean climate, which has a long, dry summer, supplemental irrigation is necessary.

The majority of commercial production is in the subtropical regions between 20° and 40° northern and southern latitudes. In the tropics, flowering is often erratic, and fruit may mature throughout the year. Although fruit size is generally large in the tropics, fruit quality is usually lower. Fruit color is generally less intense and acids may be too low for good eating quality. Yellow-fleshed and high-acid types (lemons and limes) are not as affected by these factors and are widely grown in the tropics, as are pummelos. Although there is less large-scale commercial production in the tropics, citrus is important locally and when grown for personal consumption.

In the subtropical areas, the yearly cycle of flowering and fruit development, as well as vegetative growth, is more tightly regulated by climatic conditions. This results in a crop that matures at the same time and has higher fruit quality. Semitropical conditions are intermediate between tropical and subtropical conditions. These areas, which include such major production areas

as Brazil and Florida, produce high yields of citrus that is of acceptable quality. Fruit quality for fresh consumption is lower than in subtropical climates such as California and Spain, but most fruit produced in Brazil and Florida is grown for processing, which has slightly lower-quality standards.

Within these climatic types, there are some variations in types of citrus successfully produced. For example, varieties that are colored by lycopene, such as the pigmented grapefruits, do well in these semitropical climates, while those colored by anthocyanins (blood oranges) do better in areas with lower winter temperatures. In marginal areas such as Japan and New Zealand, early maturing varieties such as Satsumas are grown.

Brazil has been the largest producer of citrus for some time, followed by the United States. Other important producing countries include China, India, Spain, Morocco, Argentina, Italy, South Africa, Australia, Mexico, and Egypt. The relative ranking of these countries varies from year to year. Recently, there has been much interest in large-scale production in countries such as China and India, where the climate is suitable and labor and infrastructure inexpensive. There are many niches

within the world citrus production. For instance, in the United States, Florida produces a large proportion of the sweet oranges, the majority of which are used in processing. California produces a higher quality sweet orange, with emphasis on navel varieties, which is eaten fresh and largely exported. Countries such as Spain and Morocco produce large quantities of mandarins for export to the United Kingdom and northern Europe. Some of the Southern Hemisphere countries export to major Northern Hemisphere producers during the off-season.

As with any industry, there have been changes over the years. In the last decades of the twentieth century, the trend has been toward increased global trade and yearlong availability in most major markets. Processed products have grown in importance. In fresh fruit, the trend has been toward easy-peeling, seedless mandarins and sweet oranges. In grapefruit, the pigmented varieties are becoming predominant.

### Production

Citrus is produced in slightly different ways in different areas. Commercial production is more uniform throughout the world than is local or personal production, but there are some differences here as well. Many of the differences are in the nature of farming inputs rather than the production of trees. For instance, fertilization and irrigation are necessary in most areas. However, a more industrialized producer in an exporting country may utilize drip irrigation with inorganic fertilizers injected through the drip system, while a producer for the local market in a poor country or area may use manure and flood irrigation.

Citrus can be grown from seed; however, there are some disadvantages. In some cases, seedlings are not true-to-type with the mother tree; due to juvenility factors, seedling trees do not usually bear fruit until they are nearly a decade old; and they are vulnerable to unfavorable soil conditions, diseases, and so forth. For these reasons, most citrus produced throughout the world utilizes budded (grafted) trees.

A budded tree consists of two parts: the scion, which is the fruit variety, and the rootstock, which supports the scion in the soil environment. Rootstocks are chosen based on a number of factors, including compatibility with the scion, resistance to diseases or pests, adaptation to soil conditions, effect on fruit quality. Citrus rootstocks can be grown from seed, since the commonly used rootstocks are apomictic (and hence true-to-type), and there are no confirmed seed-transmitted systemic diseases of citrus. Production from seed is easier than from cuttings, the common method of production for rootstocks for most other tree crops.

The rootstock is usually of an appropriate size for budding about nine months to a year after germination, when it is about the diameter of a wood pencil. The scion variety is budded onto the rootstock by making an inci-

sion into the bark of the rootstock, inserting a bud removed from the scion variety, and wrapping it with tape. A callus should form between the rootstock and scion tissues in two to four weeks. With appropriate training, the young tree is ready for planting in the field in about another year.

Once planted, it is usually about two to three years before the tree begins to produce fruit. Full production is usually achieved at about ten years of age. Under appropriate conditions, citrus trees may live a long and productive life and achieve a fairly tall height. This was common in many older citrus-producing areas. Since about the 1970s, citrus production has become more cyclical, like that of other tree crops, and the life of an orchard may be no more than twenty to thirty years.

Citrus requires relatively little cultural manipulation compared to crops such as grapes and deciduous trees, which require pruning and extensive training. In some areas, however, such as the Mediterranean basin, mandarins and sweet orange may receive somewhat more manipulation than in areas such as California. Lemons grow vigorously upright and require more frequent topping. Irrigation and fertilization are necessary. Certain production problems or challenges in citrus have been successfully managed with the application of plant growth regulators. This is more established in citrus than in most other perennial crops.

In contrast to the relatively low cultural inputs for citrus, disease and pest management in this crop is more critical and challenging than for many others. Because citrus is grown in warm areas of the world, reproduction of insect pests is rapid and insect pressure can be great. The individual insect pests vary greatly with geographic area. Compared to other crops, citrus is also subject to a larger number of systemic, graft-transmissible diseases caused by virus and viruslike pathogens that can potentially devastate industries. The most important worldwide is the tristeza virus, which destroyed many thousands of hectares in California and South America starting in the 1930s. This has been managed in some areas by certification programs requiring the use of virus-tested propagative materials and in a few cases with eradication programs. Other diseases, such as greening and citrus variegated chlorosis, are equally deadly but less widespread throughout the world.

Citrus is harvested by hand. At this point, there have not been any widely accepted methods of mechanical harvest. The time of harvest is dictated by the market or in some cases by legal maturity standards. Citrus is more forgiving than some other crops in that harvesting can be delayed somewhat and fruit quality is not decreased too much by the extra time on the tree. This varies with variety. However, if fruit are left on the tree too long, quality deteriorates as acid levels decrease and the taste becomes insipid. Other fruit quality problems can also occur. After harvest, citrus can be stored at low (refrig-

Lemon vendors in Oaxaca, Mexico. Oil painting by Mexican artist Rocio Levito, 2002. PHOTO COURTESY OF THE ARTIST.

erated) temperatures for several months. This has had important implications in the development of the industry since the beginning of the twentieth century.

After harvest, commercial citrus is transported to a packinghouse. There, the fruit is washed, sorted and graded, treated with fungicides and waxes, and packed. In some cases, ethylene gas treatment is used for de-greening. Citrus packing today is highly automated in some ways, with various sensors and other devices routing and sorting the fruit through a complexly routed pathway of conveyor belts, and bins. However, there is still a substantial amount of hand labor necessary for sorting, grading, and movement. After citrus is packed, it is transported away from the packinghouse and enters wholesale and retail market channels.

In addition to commercial production, citrus is widely grown for personal use in “door yards,” roadsides, small subsistence plots. Growing citrus for this use is extremely variable. Trees are grown from seed, are grafted by the grower, are purchased from commercial sources, and so forth. Varietal selection is based on personal preference rather than economic factors. Citrus is also prized for its ornamental value and often serves a decorative purpose as well. There are some cultivars that are grown strictly as ornamentals, such as some variegated types and the Buddha’s Hand citron.

### Use of Citrus Fruits

Citrus is consumed fresh, juiced, and processed. The most nutritious ways of serving citrus are as fresh fruit or fresh-squeezed juice. Citrus fruits are well known for their vit-

amin C content, but are also good sources of vitamin A, folic acid, and dietary fiber. Nutritional profiles of some citrus fruit and fresh juices are shown in Table 2.

Fresh citrus fruits can be stored for several days at room temperature or for several weeks in the refrigerator. Fresh-squeezed juice should be stored in the refrigerator and is stable at refrigerator temperatures for several weeks from a nutritional standpoint. However, there is often a loss of quality when fresh-squeezed juice is stored. This is especially true of navel orange juice.

Processing is an important part of the citrus market worldwide. Two of the major producers of citrus, Brazil and Florida, produce fruit predominantly for the processing trade. Low-grade and excess fruit from fresh market production may also be routed into processing. Where production is oriented toward producing citrus for processing, different varieties and to some extent different cultural practices are employed than when grown for fresh market. Criteria for harvest and quality standards are also different. Internal quality is paramount for processing citrus, whereas external appearance counts for more in fresh market fruit.

The most important use of citrus for processing is the production of frozen concentrated orange juice. The production of this is different from but equally as complex as packing fresh fruit. After fruit enter the plant, they are washed, juiced with a press or extractor, and strained to remove peel and rag. The juice then goes to the finisher, where excess pulp and essential oils are removed from the juice. It is then concentrated by an evaporator.

TABLE 2

**Nutritive value of citrus fruits and raw juices**

Fruit	Grapefruit	Grapefruit juice	Lemon	Lemon juice	Lime juice	Orange	Orange juice	Tangerine
Serving	1/2 grapefruit, raw, without peel, membrane, and seeds (3.75 in. diam., 1 lb. 1 oz., whole, with refuse)	Raw, 1 cup	1 lemon, raw, without peel and seeds (about 4 per lb. with peel and seeds)	Raw, 1 cup	Raw, 1 cup	1 orange, whole, raw, without peel and seeds (2.625 in. diam., about 2.5 per lb., with peel and seeds)	Raw, 1 cup	1 tangerine, raw, without peel and seeds (2.375 in. diam., about 4 per lb. with peel and seeds)

SOURCE: Gebhardt and Matthews, pp. 20–26.

The bulk concentrate is stored in tank farms and transported in refrigerated trucks, train cars, or ships. The bulk concentrate is packaged into consumer- or industrial-sized containers. Frozen concentrate orange juice is sometimes reconstituted into “single strength orange juice.” This is also produced directly without first being concentrated. Processing has little effect on the nutritional value of orange juice, but there is generally a loss of palatability. Grapefruit juice and to a lesser extent lemons, limes, and mandarins are processed similarly. These products are sometimes used to blend with other types of fruit juice or for the production of frozen confections. By-products of processing include essential oils and pulp. The latter is used for cattle feed. Other processed products of citrus include canned segments, segments in juice, pectin, jellies, and jams. Peel products are used for animal feed, marmalade, and shaved peel.

In addition to processing for juice and its associated by-products, there are minor industrial uses of citrus. Although essential oils are extracted as part of juice processing, in some instances trees are grown specifically for

the production of these oils. The center of this industry is Calabria, Italy, and the main variety used is Bergamot, of which there are various selections. Citrus is also used to produce pesticides, cleaning products, and hair care products.

### Health Benefits and Traditional Usage

In addition to the nutritional value and vitamin content of citrus, there are certain health benefits associated with some of the secondary products. For instance, various limonoid compounds, particularly D-limonene, have been shown to reduce tumorigenesis under experimental conditions. Carotenoids, such as lycopene, have been associated with decreased risks of heart attacks as well as general antioxidant activity. The high pectin content of some types of citrus contributes to soluble fiber consumption, which has been linked to increased cardiovascular health and reduced risk of certain types of cancer.

As might be expected with a crop utilized by humans for a number of millennia, these health benefits are reflected in the traditional use of citrus by indigenous peo-

ple. Many of these uses are focused around the center of origin in China and India. However, health-related use of citrus has also been reported from traditional peoples in such areas as Fiji, Guatemala, and Chile. Citrus has been reported to be used for treatment of various illnesses, to reduce vomiting or diarrhea, and for regulating fertility. The sour orange has been reported to be used in voodoo ceremonies in Haiti.

Many of these uses are also associated with other plants in the subfamily Aurantiodeae. The kumquats have been mentioned already as being edible, but some other types of fruits are sometimes eaten by traditional peoples. Of particular note are the use of the leaves of *Murraya koenigii* as condiments and in the preparation of curry (the common name for this tree is curry leaf) and the use of *Aegle marmelos* ("Bael") for the preparation of teas. Other traditional uses reflect some of the properties suggested by the industrial use of citrus: insecticides and shampoos. As more insight into ethnopharmacology and secondary plant products is gained, it is possible that industrial use of citrus may increase, and probably some of these uses will reflect traditional uses of these plants.

## TEMPERATE FRUIT

Many of the world's best-known and favorite fruits (such as apple, pear, peach, plum, grape, and strawberry) are adapted to climates in the middle latitudes and are known as temperate fruits. Temperate fruits have two climatic adaptations: they require some cold periods (dormancy) to complete their life cycle, which conditions their adaptation in tropical climates, and they have various degrees of winter hardiness, which conditions their adaptability in cold climates. Fruits that do not specifically require cold but have slight frost tolerance (citrus, fig, olive, persimmon, pomegranate) are known as subtropical fruits; they are not discussed here. In contrast, tropical fruits typically are very sensitive to cold and are often injured by low temperatures above freezing. Temperate fruits are usually classified by their growth habit as tree fruits (apple, pear, peach), vine fruits (grape, kiwifruit), or small fruits (strawberry, raspberry, currant, and blueberry). The term "small fruits" refers to the size of the plant and not necessarily the fruit. In the United Kingdom they are better known as bush fruits or soft fruits.

### Tree Fruits

The best-known temperate tree fruits are members of the rose family (Rosaceae). These include the pome and stone fruits. Pome fruits (apple, pear, quince, and medlar) are fleshy fruits in which the outer portion is formed by expanded floral parts and receptacle. The stone fruits, all members of the genus *Prunus* (almond, apricot, cherry, peach, nectarine, and plum) are fleshy fruits that contain a stony pit (hence the name "stone fruits"), which encloses a solitary seed.

Apple (*Malus × domestica*) is the best known of the pome fruits. It has been known since antiquity and is grown in Siberia and northern China where winter temperatures can fall as low as −40°F and in high elevations in Colombia as well as Java, Indonesia, straddling the equator, where two crops can be produced in a single year provided leaves are stripped. While there are many species of *Malus*, the domesticated kinds seem to be derived from *M. siversii* indigenous to Kazakhstan and neighboring countries where forests of wild apple contain seedlings with all of the characteristics of the domesticated sorts. Apples are popular because they can be consumed in many ways: fresh, dried, or cooked and in liquid form as juice, alcoholic cider, or brandy (Calvados). Processed apples are appreciated as a filling for many bakery items and enjoyed as a sauce or concentrated as a butter. Some apples have a long storage life under refrigeration, in some cases as long as a year, especially under controlled atmospheres (low oxygen). In the United States the apple is the symbol of wholesomeness; "an apple a day keeps the doctor away" is a popular aphorism.

Pear (*Pyrus* species) can be divided into two types, the European pear (*P. communis*), which usually are consumed when they soften after harvest, and the Asian pear

Pears are a popular winter fruit because of their storing qualities. Shown here is the heirloom Seckel pear, which was discovered in the 1790s growing wild along the Delaware River by Philadelphia wine merchant Lorenz Seckel (1747–1823). The pear is believed to be a natural hybrid of older pear varieties brought to colonial America. FROM A NINETEENTH-CENTURY WOODCUT COURTESY OF THE ROUGHWOOD COLLECTION.

(*P. pyrifolia* and *P. ussuriensis*), which are consumed when crisp. The pear is as old a fruit crop as apple but is somewhat less popular in the West. This is probably because the postharvest ripening required makes it difficult to determine optimum quality, and some fruits contain grit (stone cells), which can be objectionable. Asian pears (known as *nashi* in Japan and as *li* in China) are probably more popular than apples in China, Japan, and Korea. Pears are closely related to apples and are consumed in similar ways.

The quince (*Cydonia oblonga*) is the third most important pome fruit. It is not very popular because most are too sour and astringent to be consumed raw, but it is excellent cooked, especially in preserves, jams, and jellies, to which sugar is added. Some types grown in warm climates soften and can be consumed raw. It is an important crop in Argentina. Some quinces are used as dwarfing rootstocks for pear. Quinces have a wonderful perfume and should be more widely grown but have passed into the realm of a neglected fruit. The Asian quinces (species of *Chaenomeles*) are often grown as or-

namamentals, but there have been attempts to domesticate these species in the Balkans for juices and preserves.

Medlar (*Mespilus germanica*) is truly an almost forgotten fruit. It is mentioned and disparaged by Shakespeare, who notes that it must be almost rotten to be enjoyed. The medlar is inedible until an internal fermentation occurs, producing an aromatic taste that appeals to some. The medlar can still be found in Italian markets.

The peach, despite its scientific name (*Prunus persica*), which suggests a Persian origin, is native to China, where it has always been highly prized for the beauty of its flowers and fruit. The peach seems to have been introduced to Europe via Persia in the first century B.C.E. but may have been known to the Greek philosopher Theophrastus (372–287 B.C.E.), who writes of Persian fruit and Persian apple. The fruit was well known to the Romans, and pictures of peaches were found in Herculaneum, destroyed in the eruption of Vesuvius in 79 C.E. Peach germplasm was introduced to the United States by the Spanish in the sixteenth century and became naturalized, but quality was low. Introductions from China in the middle of the nineteenth century, particularly one called Chinese Cling, are the progenitors of modern American cultivars. Peach is now the most popular temperate summer fruit. There are a number of distinct types. The freestone types with melting flesh and white or yellow flesh are usually consumed fresh. The clingstone, rubbery-flesh types are used in processing. The nectarine, a peach with a nonfuzzy skin, resulted from a mutation. Peentao, a saucer-shaped, flat peach is another variant type. Breeding in the United States has created many cultivars of both peach and nectarine that are widely grown in Europe, and some have been reintroduced to China for greenhouse production.

Almond (*Prunus amygdalus*) is native to the hot arid regions of western Asia but was introduced to Greece and West Africa in prehistory. The flesh is leathery and inedible, although the very immature fruits are consumed in Arab countries. Unlike most stone fruits, which have a bitter seed due to hydrocyanic (prussic) acid, the seeds of almond are nonbitter and are the edible part of this fruit. This species is therefore discussed under nuts. The almond is the most extensively planted “fruit” in California and is widely grown in countries of the Mediterranean basin.

Cherries, one of the most popular early summer fruits, are a symbol of joy as expressed in a famous song line: “life is just a bowl of cherries.” There are about thirty species of cherry. The edible types include sweet cherry (*Prunus avium*), a diploid with two sets of chromosomes ( $2n = 16$ ), and tart (sour) cherry (*P. cerasus*), a tetraploid with four sets of chromosomes ( $2n = 32$ ). Another tetraploid type called Duke cherry is derived from a hybrid between sweet and tart cherries. Cherries may be red, yellow, or bicolored and are consumed fresh, dried, or processed, including as a liquor called kirsch.

The Maraschino cherry is almost an artificial fruit in which cherries are brined, bleached, and then artificially colored and flavored with bitter almond oil. They are often used in a wonderful confection: chocolate-covered cherries. Cherries are now available over a long season in North American markets due to the efforts of American and Canadian breeders.

Apricot (*Prunus armeniaca*), an ancient fruit native to central Asia and China, was thought by the Greeks to have originated in Armenia, hence its scientific name. The beautiful, aromatic fruit with a velvety skin is consumed fresh, dried, and processed. Apricot liquor is well appreciated. The apricot blooms very early, is subject to spring frost, and is difficult to grow. This may explain why apricot has not become as important as peach, cherry, or plum. The beautifully flowered Chinese plum (*P. mume*) is more properly included with the apricots than the plums.

Plums are a diverse group of fruits, as exemplified by the many names by which they are known: bullaces, cherry plums, damsons, date plums, egg plums, greengages, mirabelles, plums, prunes, and sloes. Various species originated in Europe, Asia, and America. Two European species (*Prunus domestica* and *P. insititia*) are hexaploid, with six sets of chromosomes. The *domestica* plums include several groups of cultivars, such as greengage and prune types, while *P. insititia* includes bullaces, damsons, mirabelles, and St. Julien types. Among Asiatic species are *P. salicina* and *P. simonii*, the former of which includes both red- and green-fleshed Japanese plums. Many of these were introduced by Luther Burbank, with the red-fleshed Santa Rosa being the best known. *P. simonii* (apricot plum) is cultivated in China. There are a number of American plum species, but none are widely cultivated. At the start of the twenty-first century, the world plum industry is largely made up of *P. domestica* in Europe and *P. salicina* in Asia. Plums are consumed fresh or dried. Plums that dry without fermentation are called prune plums or simply prunes. They are dried down to very low moisture levels, in which state they can be stored for long periods of time. They are rehydrated when they are sold as packaged prunes, processed into jelly and jam (popular as a bakery filling), made into a diluted juice, or turned into brandy or cordials. The wrinkled dried fruit was widely consumed by senior citizens because of its laxative properties and thus became a source of comic derision. (It has been said that the turndown service at senior hostels includes a prune rather than a chocolate on the bed.) As a result, the industry has changed the name of prune to dried plum!

### Vine Fruits

Grapes (species of *Vitis*, Vitaceae, or grape, family), one of the most important temperate fruit species, are usually grown on trellises. Total world production of this fruit is surpassed only by all citrus and species of *Musa* (banana and plantain). Grapes derived from the European species, *V. vinifera*, have been prized as the source of wine since antiquity. Although wine can be made from

any sweet fruit, the grape is the preferred species because the combination of sugars, acids, and astringent substances such as tannins gives character to the product. The name of wines, such as cabernet sauvignon and pinot noir, refer to the grape cultivar. Because these wines have become a standard product there is great reluctance to change grape cultivars used for wine, but various clones have been selected throughout the many years they have been cultivated. Some grapes (known as table grapes) can also be enjoyed fresh; many of the new cultivars bred for this purpose are seedless. Nonalcoholic grape juice is enjoyed in the United States; this industry derives from Concord, a cultivar of the American species *V. labrusca*, the fox grape. American grapes are typically winter-hardy and have a slip skin and a unique flavor referred to as foxy. Concord juice in the United States is also used to make the sweet wine used traditionally in Jewish ceremonies, a product often derided by wine connoisseurs but still enjoyed by millions of ordinary folk. (When the astronaut Gene Cernan landed on the moon, he expressed his wonder at the sight with the famous expression "Man O Manischewitz," the name of a popular brand!) American grapes have long been grown in Japan, where their foxy flavor is appreciated. The large-fruited table grape Italia, widely appreciated in Europe, has a muscat flavor that is similar to the foxy flavor of *labrusca* grapes, many of which are sweet and pleasant but insipid. The strong-flavored muscadine (*V. rotundifolia*), native to the southern United States, has a small market in this area for fresh fruit, juice, and wine.

The kiwifruit (*Actinidia deliciosa*, Actinidiaceae) is an example of a fruit species that has been essentially domesticated in the twentieth century. It derives from a gathered Chinese fruit known as yangtao, which had long been appreciated in China but was collected rather than cultivated. Introduced to the United States and New Zealand early in the twentieth century by the plant explorer E. H. (Chinese) Wilson, it was referred to as Chinese gooseberries. Although it remained a curiosity in the United States, New Zealand growers and nurserymen succeeded in domesticating the crop by selecting suitable male and female clones (the plant is dioecious), as well as techniques for cultivation. One seedling selected by A. Hayward Wright and subsequently named Hayward became the mainstay of the world industry. The fruit was exported to the United States and promoted by Frieda Caplan, a marketer of new crops. In 1959 the relatively unattractive brown fruit received the new name kiwifruit after the kiwi, an endemic flightless bird often used as a nickname for New Zealanders. Kiwifruit has a pleasant but weak flavor with very high vitamin C content, but the nutritious quality of the fruit has not been promoted; rather, it was the beautiful and unique appearance of the sliced flesh, which is used as a garnish on bakery products or as a component of mixed fruit, that made this fruit popular worldwide. The long storage life of the fruit made it possible for New Zealand to export the fruit

year-round. The popularity of the crop made millionaires of many New Zealand growers, but as kiwifruit began to be grown in such countries as the United States, Italy, and Chile, the boom crashed and New Zealand growers had to struggle to survive. Kiwifruit is consumed out of hand in New Zealand, usually scooped with a spoon, but this technique has not caught on, and further expansion is probably linked to development of a simple method for peeling. A yellow-fleshed kiwifruit marketed as Zespri Gold (*A. chinensis*) was introduced at the turn of the twenty-first century, and the New Zealand growers are attempting to control its distribution. It is too early to know if this will succeed. A small-fruited hardy American species (*A. arguta*), sometimes called tara fig, is now cultivated in gardens but this species has not been commercialized.

### Small Fruits

Strawberry, the most widely grown small fruit, has an interesting history. Although a small-fruited species of strawberry (*Fragaria vesca*, a diploid species,  $2n = 16$ ) is native to Europe, the modern strawberry is derived from hybrids between two octoploid ( $2n = 56$ ) native American species, *F. virginiana*, indigenous to the East Coast of North America, and *F. chiloensis*, native to Chile. Hybrids between these two species were produced naturally in Brest, France, early in the eighteenth century when a pistillate clone of the large-fruited *F. chiloensis*, introduced by Amedée François Frezier, a French army officer, was interplanted with staminate plants of *F. virginiana*. The new hybrids (now known as *Fragaria*  $\times$  *ananassa*, or pineapple-strawberry) initiated the modern strawberry industry. Breeding efforts through the years have resulted in tremendous advances as the plant was changed from a predominantly dioecious species with male and female plants to a hermaphroditic species, in which flowers contain both stamens and pistils. Fruit size has been greatly increased, and modern cultivars tend to be very firm-fleshed (too firm for some), with improved flavor and appearance. Although strawberries are grown in all temperate countries, the industry is now concentrated in some favored locations such as southern California in the United States, southern Spain, and various locations in Italy. Some strawberries now are grown in greenhouses.

The genus *Rubus* is very diverse. The cultivated *Rubus* species known as brambles includes red raspberry (*R. idaeus*), black raspberry (*R. occidentalis*), and blackberry (*Rubus species*), including various interspecific hybrids between raspberry and blackberry, such as loganberry, boysenberry, and tayberry. Brambles have delicious flavors but marketing has been a problem because of the soft texture of the fruit.

Cultivated species of *Vaccinium* and *Ericaceae* are berry crops domesticated in the twentieth century. Blueberry (various species) is native to the United States and grows in bushes of various heights. The blue fruits are easy to preserve by freezing and have become very pop-

ular in the United States because of their use as a fresh fruit and in muffins or pancakes. They are increasing in popularity in Europe and in New Zealand. The cranberry (*V. macrocarpon*) is an unusual berry crop because it is grown submerged in bogs. The fruits are too acid to be eaten raw and are consumed processed as jelly or as a sauce. In the United States cranberry is a favorite food for the feast of Thanksgiving. Sweetened dilute cranberry juice, consumed alone or mixed with other fruit juices, has become popular because of its therapeutic benefits in urinary tract problems of women. Lingonberry (*V. vitis-idaea minus*) is native to northern regions of Europe, Asia, and North America. The bright red fruit has long been gathered from wild stands in Scandinavia, and a large commerce developed from this source. Attempts to domesticate the crop are based on the management of natural stands. There are a number of other native *Vacciniums*, such as bilberry (*V. myrtillus*) and bog bilberry (*V. uliginosum*), that have been considered as possible domesticates.

Cultivated *Ribes* species include a number of popular berries such as black currant (*Ribes nigrum*), red and white currant (*R. sativum* and *R. rubrum*), and gooseberries (*R. grossularia*). They are too acid to be consumed fresh and are essentially used for jams, jellies, and juice. Black currant was the source of ribena syrup, widely fed to British children during World War II as a source of vitamins. Black currant is not widely grown in North America because cultivation was discouraged and even made illegal because the plants were alternate hosts for white pine blister rust.

### TROPICAL AND SUBTROPICAL

Tropical and subtropical fruits, in contrast with temperate fruits, can be broadly defined as those meeting all of the following criteria: crops that have their origin and commercial growing areas (when such exist) in the tropics or subtropics, plants that are evergreen and perennial, crops with a limited degree of frost resistance, and plants

whose growth is practically nonexistent below 50°F (10°C) (with some exceptions according to species and individual age). A distinction between tropical and subtropical is possible if one considers that tropical species are not only sensitive to temperatures below 68°F (20°C) but indeed require a climate with average mean temperatures higher than 50°F (10°C) for the coldest month (Watson and Moncur, 1985, p. 3). Additionally most tropicals require humid environmental conditions. Examples of truly tropical crops are traditional fruits native to Southeast Asia, like mangosteen, durian, and rambutan. A good example of a typical subtropical fruit crop is the cherimoya, which when cultivated in cold subtropical areas may suffer some foliage loss during the winter with regrowth in spring. However, some fruit crops can be cultivated equally well in either the tropics or the subtropics, of which the banana and the avocado are the most outstanding examples.

Strictly speaking, the tropics extend between the Tropics of Cancer and Capricorn, at 23° north and south of the equator. But, agronomically speaking, these boundaries are too rigid. Not only do they contain areas, especially at higher altitudes, that do not conform to the climatic characteristics generally assigned to the tropics, but regions outside this belt have coastal areas or insular climates that may exhibit climatic conditions fitting properly in the tropics. This is the reason why some climatologists have extended the region to the thirtieth parallels (Nakasone and Paull, 1998, p.1). In any event the main feature associated with the tropics is not so much that of heat but rather steady warm temperatures throughout the year. J. A. Samson (1986, p. 1) gave a good working definition of the tropical climate: temperature averages around 80.6°F (27°C), with the warmest month being only a few degrees higher than the coldest and temperature differences between night and day, at any given time, being greater than those between winter and summer, and, finally, little variation in day length, with the longest day being less than thirteen hours long. In comparison, the subtropics have hotter summers and cooler winters. Humidity is also generally lower. Day length differences become greater with increased latitude. The limit for the subtropics is the isotherm of 50°F (10°C) average for the coldest month (Nakasone and Paull, 1998, p. 12).

Hundreds of tropical and subtropical fruits exist, but only some fifty are well known throughout most of the world (Martin et al., 1987, p.1). These are important production crops (see Box 1), although a considerable gap exists between world per capita consumption (54.9 kilograms per year) and estimated consumption saturation (about 100 to 120 kilograms per year) (Jansen and Subramanian, 2000). Production and trade figures allow the division of tropicals and subtropicals into three main categories (Galán Saúco, 1996) with some overlapping.

1. Major fruits, such as banana and plantain, citrus, coconut, mango, and pineapple.

2. Minor fruits, such as abiu, atemoya, avocado, breadfruit, carambola, cashew nut, cherimoya, durian, guava, jaboticaba, jackfruit, langsat, litchi, longan, macadamia, mangosteen, papaya, passion fruit, pulutan, rambutan, sapodilla, soursop, and white sapote.
3. Wild fruits belonging to diverse botanical families. These are not cultivated commercially in any country and are much in need of characterization, conservation (both in situ, including on farm, and ex situ), selection, and breeding.

Major-category fruits are cultivated in most tropical (and subtropical) countries and are well known in both local and export-import markets. Minor fruits are not so extensively cultivated, and consumption and trade tend to be more limited, both geographically and quantitatively. However, many are of considerable economic importance in their respective regional markets, as is the case with carambola, durian, and mangosteen, which are major fruits throughout Southeast Asia (Anang and Chan, 1999).

**TABLE 1**

**Production of major tropical and subtropical fruits in 2000**

Fruit	World production (x 1,000 t)	Important producing countries
Orange	66,055	Brazil, United States, India, Mexico, Spain, China, Italy, Egypt, Pakistan, Greece, South Africa
Banana	58,687	Burundi, Nigeria, Costa Rica, Mexico, Colombia, Ecuador, Brazil, India, Indonesia, Philippines, Papua New Guinea, Spain
Coconut	48,375	Indonesia, Philippines, India, Sri Lanka, Brazil, Thailand, Mexico, Vietnam, Malaysia, Papua New Guinea
Plantain	30,583	Colombia, Ecuador, Peru, Venezuela, Ivory Coast, Cameroon, Sri Lanka, Myanmar
Mango	24,975	India, Indonesia, Philippines, Thailand, Mexico, Haiti, Brazil, Nigeria
Papaya	8,426	Nigeria, Mexico, Brazil, China, India, Indonesia, Thailand, Sri Lanka
Avocado	2,331	Mexico, United States, Dominican Republic, Brazil, Colombia, Chile, South Africa, Indonesia, Israel, Spain
Pineapple	13,455	Philippines, India, Indonesia, China, Brazil, United States, Mexico, Nigeria, Vietnam

## Botanical Aspects

Tropical and subtropical fruits include not only woody plants, such as the mango or the orange, but also herbaceous crops like the banana and vines like the passion fruit. Most botanical families can lay claim to at least one species of tropical or subtropical fruit. Franklin Martin and colleagues (1987) list some 137 families, and the best known are in Box 2.

From the botanical point of view, a fruit is the structure developed from flowers or inflorescences. In most cases the fruit consists only of the developed ovary, but it may include other parts of the flower, such as the pedicel, sepal, or receptacle, or even a portion of the seed stalk. As with temperate crops, many different fruit types appear among the tropics and subtropics, from single fruits, including berries, such as the avocado or orange; drupes, such as the mango; pomes, such as the loquat; capsules, such as the durian; nutlets, such as the litchi and the longan; to compound fruits, as in the typical syncarpium of the pineapple; or even a bunch of individual berries, as in the banana. To differentiate fruit crops from perennial vegetables whose fruits are also eaten, it is necessary to keep in mind that in a horticultural sense a fruit is something that is normally eaten fresh and out of hand. A number of exceptions exist, like the breadfruit and the plantain, considered fruits by all but only palatable when cooked, as if they were vegetables. Nuts, obviously not eaten out of hand, and some tree crops whose seeds are the only part eaten, are also included among tropics and subtropics in most horticultural books and as such are included in this entry.

TABLE 2

### Best-known tropical and subtropical fruits and their botanical families

Family	Common names of species
Anacardiaceae	Mango, Cashew
Annonaceae	Cherimoya, Guanábana, Custard apple
Bombacaceae	Durian
Bromeliaceae	Pineapple
Cactaceae	Pitaya
Caricaceae	Papaya
Ebenaceae	Caki
Guttiferae	Mangosteen
Lauraceae	Avocado
Malpigiaceae	Acerola
Meliaceae	Langsat or Lanson
Moraceae	Breadfruit, Jackfruit
Musaceae	Banana, Plantain
Myrtaceae	Guava
Oxalidaceae	Carambola
Palmaceae	Coconut, Date
Passifloraceae	Passion fruit, Granadilla
Proteaceae	Macadamia
Rosaceae	Loquat
Rutaceae	Orange, Grapefruit, Mandarin
Sapindaceae	Litchi, Longan, Rambutan
Sapotaceae	Chicosapote, Lucuma
Solanaceae	Sweet pepino, Lulo, Tamarillo

## Areas of Origin and Spread

Although most of the continents, including the islands throughout the Pacific, have contributed tropical and subtropical fruits (see Box 3), most of the best-known ones came from the tropical and subtropical regions of America (for example, papaya, avocado, pineapple, guava) and Asia (for example, orange and most citrus fruits, mango, banana, litchi). Only two commercially important fruits originated in Oceania, the macadamia in Australia (specifically Queensland) and the coconut in the Pacific, the latter to the extent that its origin is considered pantropical (Martin et al., 1987, p. 47). The only important fruit native to the African continent is the date. Europe, with no tropical and limited subtropical areas, has none.

Spread to the regions surrounding their areas of origin probably began early, as soon as humans realized their value in terms of nutrition and the variety they could add to the primitive diets of the time. The potential of some species to provide not only food but also shelter or clothing (some types of banana), wood, and medicine hastened distribution.

An outstanding example is the mango. Native to the Indo-Burman region, by the end of the fourth century C.E. it had spread to all the tropical countries of Southeast Asia (Galán Saúco, 1999, p. 36). The Arabs were apparently responsible for its spread to the east coast of Africa around 700 C.E. as an adjunct to their slaving ventures. Just as Malaysians introduced the banana to Madagascar some two centuries earlier, Islamic domination brought the orange to the Mediterranean and southern Europe. Crops from the Americas are not as well documented, but archaeological findings have shown connections between the cultures of Mexico and Peru dating as far back as 1000 B.C.E. (Purseglove, 1968, p.12), giving a solid opportunity for some tropical and subtropical fruits to spread around the warmer American lands.

Soon after the European discovery of America, the Old and New Worlds rapidly exchanged crops. The sixteenth-century monk Bartolomé de las Casas mentioned that orange seeds were carried from the island of La Gomera (Canary Islands, Spain) to Haiti on Christopher Columbus's second voyage in 1493 (Amador de los Ríos, 1851–1855, vol. 1, p. 3). It is similarly well documented that the banana was carried to Santo Domingo from the Canary Islands in 1516 (the Canaries were a routine last port of call for European ships facing an Atlantic crossing). After Columbus's voyages, a veritable avalanche of expeditions explored all corners of the world, and where the ships went, food went also, to say nothing of tasty fruits and easily propagated species. Between 1500 and 1650 Portuguese sailors connected Brazil and the Cape of Good Hope, touching Goa, Malacca, the Moluccas, Canton, and Macao, trading from there with Japan and Formosa. The Spanish Manila galleon route dominated shipping from 1565 to 1815, plying the seas between the Philippines and Mexico. Dutch, British, and French voy-

agers were also important in spreading tropical fruits around the world.

No hard and fast rule explains why some fruits spread quickly throughout the world while others remain limited in scope even in the twenty-first century. Several factors may be involved, among them crop adaptability, shelf life, ease of propagation (including the capacity to survive long voyages), size of the plant, multiplicity of uses (that is, other than as fresh fruit), and taste acceptance.

The excellent taste of the pineapple, the long-lasting viability of the plant's suckers as planting material, and the rapidity with which it produces fruit all account for its prompt appearance in Europe—albeit in glasshouses—and India as early as 1548 (Nagy and Shaw, 1980, p.16; Galán Saúco, 2001). Similar considerations apply to the banana and the papaya and even to woody perennial trees like the mango or the guava, which soon spread throughout the tropics and subtropics, even though their size precluded cultivation in greenhouses outside these areas. On the other hand true tropical trees are usually demanding in climate and in some cases are difficult to propagate. The mangosteen, rambutan, and durian (this last deemed by many people to have a peculiar taste) have remained confined almost exclusively to their area of origin in Southeast Asia. The mangosteen is notable among tropical fruits in that it has proven particularly intractable to most attempts to establish it outside of its area of origin via the usual method, which is selection or breeding of cultivars capable of adapting to environments different in climate or edaphic conditions. The species consists of a single genotype, which in essence means no genetic variation exists with which to breed or improve stock, and it is entirely possible that its evolution has ceased (Yaacob and Tindall, 1995, p. 25).

### Nutritional and Medicinal Value

Despite the relatively low caloric values of tropical and subtropical fruits (banana and plantain and avocado are the notable exceptions), they play an important role in human diet mainly because of their high and diverse vitamin and mineral content. This has been of capital importance in the tropics, where people have been consuming them since ancient times, either by collecting fruit from the wild or by cultivating plants in kitchen gardens. They have become an important part of the diet of people in the developed countries of the world, especially among the health and fitness conscious. In a properly balanced diet, tropical and subtropical fruits may be an excellent component for the sports-oriented person. This is not to say that one can live by tropical fruits alone or that they can be considered staple fruits within the diet (again the banana and especially its relative the plantain are the exception in some tropical areas). But nutritionists have long recommended a minimum of one hundred grams of fruit per day and that it be as varied as possible. Toward the end of the twentieth century market campaigns commonly recommended consumption of five

A traditional Greek fig wheel, showing the manner in which figs were dried and shipped since ancient times. This photograph dates from 1910. ROUGHWOOD COLLECTION.

fruits per day, which, while it may have more to do with commerce than with science, does reinforce the value of fruit as a part of the human diet.

Tropical and subtropical fruits also have some medicinal properties. Many tropical fruits, notably the mango and the papaya, are a good source of carotene (provitamin A). An indication of the high content of this vitamin is the orange-yellow color of the flesh. Others, like all citrus fruits and the guava, are well known as good sources of ascorbic acid (vitamin C). In general they are not a good source of the B group of vitamins (thiamine, riboflavin, and niacin) except for nuts, which are also a good source of vitamin E, proteins, and fats (Martin et al., 1987, p. 7). Tropical and subtropical fruits are also rich in pectin, fiber, and cellulase, which promote intestinal motility. In common with other fruits, they are good sources of antioxidants, and some are also good sources of organic acids, which stimulate appetite and aid digestion.

Values for the chemical composition of tropical and subtropical fruits are widely available in many texts, some of which are included in the bibliography cited here, but the salient points related to general nutritional value follow. Banana is a good source of vitamins A, B, and C and riboflavin. Together with the tropical and subtropical nut fruits, the banana has the highest calorie content. It is low in protein and fat and rich in potassium. Easy to

digest, it constitutes an excellent food for young and old alike and is recommended for athletes. Avocado has a good oil content (of the different avocado races, the West Indian types have the lowest) composed of highly digestible unsaturated fatty acids, and it is rich in folic acid. Some cultivars contain good quantities of proteins, vitamin A, riboflavin, and phosphorus.

All citrus fruits have fairly high amounts of vitamin C, as does the guava, which in turn contains fair amounts of niacin and iron. The papaya has high quantities of vitamins C and A as well as potassium and calcium, and it is low in carbohydrates. However, its outstanding feature, which distinguishes the papaya from all other fruits, is the fact that it contains papain, an enzyme that promotes digestion (although papain content does decrease as the fruit ripens). It is highly recommended for people with certain digestive disorders. The mango is rich in provitamin A and carbohydrates and is an acceptable source of vitamin C. The same is true of the passion fruit, which additionally has acceptable quantities of niacin. The pineapple is also rich in vitamin C and carbohydrates and is a good source of calcium, phosphorus, iron, potassium, and thiamine.

The litchi and the longan, most of the Annonaceae, and the durian are all good sources of carbohydrates and vitamin C. The durian also has fair amounts of iron and niacin. The mangosteen is considered by many to be one of the finest tasting fruits of all, according to the title of “queen of fruits” (Yaacob and Tindall, 1995, p. v). It is one of the lowest in nutritive value, but even so it can boast moderate quantities of calcium, phosphorus, ascorbic acid, and carbohydrates. The carambola is low in calories and rich in vitamin C, and it is an adequate source of vitamin A. It is prohibited for people with kidney problems (specifically stone formation) due to its high oxalic acid content, but new cultivars have been selected for lower oxalic content while maintaining sugar and vitamin levels (Galán Saúco et al., 1993, p. 5).

The macadamia nut is rich in protein, oil, iron, calcium, thiamine, riboflavin, and niacin. The subtropical date also has a high nutritive value. Rich in carbohydrates, it is a good source of vitamin A, potassium, and iron but is low in oils and sodium. The coconut is high in phosphorus, iron, proteins, and oils—in this case all saturated fatty acids, the consumption of which should be limited according to health recommendations. Coconut milk aids in balancing pH in the body due to its alkaline reaction.

The medicinal value of tropicals and subtropicals, both the fruits themselves and their actual plant parts (bark, roots, and even pollen), has long been acknowledged by the diverse peoples in and around their areas of origin. These regions are rich in recipes for preparing infusions, decoctions, syrups, pastes, jellies, juices, and so forth for myriad purposes. All the citrus fruits and several others rich in vitamin C are obviously useful to prevent colds and similar infections, while fruits rich in vitamin A

prevent dietary deficiencies, such as those leading to blindness. An excellent compilation of popular medicinal uses is in the book *Fruits of Warm Climates* (1987), written by Julia F. Morton, but a few examples follow.

The date has a high tannin content that is reportedly useful as an astringent in intestinal complaints and is good for sore throats, colds, and bronchial catarrh. Breadfruit is reported to reduce high blood pressure. Carambola fruit and pineapple juice are reportedly useful diuretics, while the flesh of the very young fruit of the pineapple is reputedly an abortifacient. The skin of the avocado and extracts of ripe and unripe fruits and seeds of the papaya reportedly have antibiotic properties. In traditional medicine a decoction of young mango leaves is recommended as a remedy for asthma, blenorraghia, and bronchitis. The roots, bark, leaves, and immature fruits of many tropical fruit crops are widely used in the tropics as astringents to stop gastroenteritis, diarrhea, and dysentery. A decoction of the boiled fruit of the sapodilla has also been reported useful in treating diarrhea. The flesh of the longan has been recommended for its febrifuge and vermifuge properties and as an antidote against some types of poisons. The infusion of passion fruit leaves, rich in the glycosid passiflorine, is reported to have sedative properties.

### Consumption and Other Uses

The main method of consumption of most tropical and subtropical fruits is as fresh fruit. The breadfruit is the most important exception, as it is only eaten cooked. Nuts can be eaten directly or processed (roasted, candied, and so forth). Salads, both savory and sweet types, are prepared with many fruits. Indeed consumption is virtually as unlimited as the chef's imagination. Jams, jellies, juices (made with fresh fruits, concentrates, or frozen pulp), sauces, ice cream and sherbets, and other desserts and diverse confectionaries are typical of the uses to which tropical and subtropical fruits are put, both industrially and domestically. Infusions as social beverages, not as medicinal remedies, are made from many different fruits.

A specific product is baby food, especially made with “healthy” fruits like the banana or the papaya, based on different kinds of puree (industrially known as aseptic, chilled aseptic, or simply chilled purees). Flour is also made from the durian and the banana. Pickles and chutneys are made from many fruits, the most famous of which is mango chutney, a staple in Indian cuisine and highly esteemed by gourmets. Dips are also popular in many countries, of which perhaps the best known is avocado-based guacamole. Guava paste or spread is consumed, usually with bread and cheese, in many countries, particularly Cuba, Brazil, and the Canary Islands.

Besides their edible and pleasant fruits, the actual plants of several tropical and subtropical fruit crops are also put to good use. Descriptions of the many properties of parts other than fruits—wood, leaves, flowers,

roots, seeds—are frequently dealt with in older texts (including, among others not yet mentioned, Popenoe, 1974 [1920]; Chandler, 1958; Singh, 1960; Purseglove, 1968; Ochse et al., 1972; Coronel, 1983), but a clear dearth of in-depth studies on many of these aspects is apparent. The potential of leaves or flower extracts as biological products for use against pests and diseases is in much the same situation and is an issue relevant to organic produce, of increasing importance to concerned consumers. Some outstanding examples of alternative uses follow.

**Religious uses.** Some orchards of date palms in the Mediterranean are maintained solely to supply young leaves used on Palm Sunday during the Christian Easter week.

**Oils, perfumes, and the like.** An essential oil is extracted from some citrus species, particularly from certain oranges and their flowers. Avocado oil, occasionally used for cooking, is a commercial product in some countries. Soaps, bath gels, and shampoos include extracts from different tropical and subtropical fruits. Loquat seed oil is used in soaps and paints.

**Animal feed.** Banana leaves, pseudostems, and fruits are fed to goats in several countries, particularly in the Canary Islands (Galán Saúco, 2001). Dried dates and their pits, breadfruit leaves, and mango seed kernels are used as feed in several countries. In India, Gandhi recommended using peanuts and mango seed kernels rather than expensive cereals and imported fodders (Galán Saúco, 1999, p. 44).

**Textiles and paper.** Fibers from pineapple and banana leaves are used in several places for papermaking and cloth, notably in the Philippines to make the typical loose-fitting shirts called *guayaberas*.

**Handicrafts.** Mature date palm leaves and avocado wood are excellent for decorative carvings.

**Construction and furniture.** The wood of breadfruit, citrus in general, guava, longan, mango, and mangosteen are regularly used for interior paneling or for furniture. The wood of the *caki* is highly prized. Banana and date palm leaves are a traditional roofing material in many regions.

**Firewood.** Orange wood is long lasting, while avocado wood is highly combustible. Mango wood is held in high esteem in Bangladesh, to the extent that the locals consider the best trees those that faithfully provide both wood and fruit (Galán Saúco, 1999, p. 44).

**Other uses.** For many years chewing gum (*chicle*) was made from *sapodilla* latex. Although the industry subsequently began to use artificial substances, the trend in favor of organic products may signify a return to traditional *chicle*. Garden brooms are made out of the stripped fruit clusters of the date palm. Fishermen in the Pacific have used the coconut as a fishing aid, chewing the coconut

Dates, figs, jujubes, citrons, oranges, pomegranates, and a rich array of other fruits crowd this enticing stand in the market at Kairouan, Tunisia. © DAVE BARTRUFF/CORBIS.

meat and spitting the resulting mass onto the water to produce a glossy calm spot, smooth enough to allow a brief glimpse of the fish below the surface (Hawaii).

The potential for development of tropical fruits does not rely only on consumption. Planting tropical fruits for agroforestry and for urban horticulture are important endeavors. In fact tropical countries like Malaysia encourage and promote intercropping of suitable perennial fruits with compatible forest species (Anang and Chan, 1999). Many tropical fruit trees make beautiful ornamental plants not only capable of improving air quality but also capable of contributing to ecological stability. They are easy to handle in gardens or in industrial or community buildings and are adequate for planting along country roads. These considerations may involve new lines of research, particularly searching for cultivars that can be oriented toward wood (or flower) production. As indicated at the World Conference on Horticultural Research (WCHR) held in Rome in June 1998, international agencies and local authorities should work together with university and government scientists to promote the

## DATES

The date palm (*Phoenix dactylifera*) has been cultivated in the Middle East since ancient times, where it has assumed a role as more than simply a source of food and become culturally associated with Islamic culture. In the words of the Prophet Muhammad, "There is among trees one tree which is blessed . . . it is the palm."

The date palm is adapted to areas with long, very hot summers with little rain, low humidity, and abundant underground water. This is expressed by the saying that the date palm "must have its feet in running water and its head in the fire of the sky." These conditions are found in oases and river valleys in the arid subtropical deserts of the Middle East, the area of origin of the date palm. This is the "Fertile Crescent," where agriculture in the Old World is thought to have arisen. The date palm has been cultivated in this area since about 7000 B.C.E., and was possibly one of the first crops domesticated. By 2000 B.C.E., date palm culture had spread to Palestine, Arabia, Egypt, North Africa, and western India.

Date palms or their wild progenitors were undoubtedly used by man even before actual cultivation began. A date palm oasis must have been a welcome sight to those crossing the desert. Here were water, shade, and fresh and dried fruits high in carbohydrates. The dried fruits were easily stored and transported after leaving the oasis. The date palm also supplied building material, fiber, fuel, animal feed, honey (syrup), and wine.

The date palm had great spiritual and cultural significance to peoples of the region. It is depicted on many ancient tablets, bas-reliefs, and so forth. The date palm is mentioned a number of times in Jewish and Christian writings, but achieved its greatest esteem in Islamic culture. The date palm was consecrated by Muhammad in both his public and private life, and is prominently mentioned in the Koran and in other Islamic writings. Date consumption spread from Arabia along with Islam, and dates are now eaten by Muslims in areas unsuitable for their production, such as Indonesia and Thailand. Date culture

eventually spread to non-Islamic countries with suitable growing conditions, but its culture and consumption in these areas is minor compared to that in the Islamic world.

In the early twenty-first century, the Middle East is still the center of date production and consumption. The largest producers of dates are Egypt, Iran, Iraq, and Saudi Arabia. Most dates are consumed locally, but there is some export, mostly to other Islamic countries that do not have suitable growing conditions. Production of dates is highly specialized and labor-intensive. There are great variations in date growing practices: from traditional oasis culture to modern industrial plantings. The United States has led the way in mechanization of date production, but this practice is spreading to other countries as they modernize.

There are thousands of local varieties of dates grown in the Middle East. Other countries have a more limited number of varieties derived from a few importations. Recently, *barhee* and *medjool* have become increasingly prominent due to their use as foundation materials for tissue-cultured plants. The use of tissue-cultured plants has become common in some countries as the increase in land area devoted to date culture has expanded beyond that which can be planted with offshoots, the traditional method of propagation.

Dates are consumed fresh or in processed form. Fresh market dates are divided into dry, semidry, and soft varieties. In Middle Eastern countries, they are also eaten in the early *khalal* stage. Dates are nutritious, being high in carbohydrate and fiber. In most varieties, the sugar content is mostly invert sugar (glucose and fructose), with only low levels of sucrose. Processed products are more common in the Middle East, where large amounts of dates are produced, than they are elsewhere. Processed products include sugars, pastes, flours, preserves, syrups, and fermentation products.

*Robert R. Krueger*

utilization of horticultural plants in large metropolitan areas (Gosselin et al., 1999).

### Commercialization and Trade

In addition to citrus and the banana, four other tropical and subtropical fruits, pineapple, mango, avocado, and papaya, dominate the fresh fruit export trade (see Box 4). Pineapple clearly leads the ranking in processed fruits with a wide range of products, although juice and rings in syrup are the best known.

Many other tropical and subtropical fruits are no longer exotic products in world markets, having become firmly established with guaranteed supply and reasonable prices. Carambola, guava, litchi, mangosteen, passion fruit, and rambutan have experienced notable development. The main importers of most of these tropical and subtropical fruits are the European Union, the United States, Japan, Canada, and China.

Exports of fresh fruits are mainly by ship or surface transport. Postharvest techniques for extending the shelf

life of most tropical and subtropical fruits have been mastered, and refrigerated boats (some even providing controlled atmosphere installations) move these commodities from production countries to their ultimate markets with ease. A small proportion of the major fruits, particularly pineapple, mango, and papaya, are transported by air, either destined specially for gourmet or niche markets or for celebrations at certain times of the year, such as Christmas and New Year's, when they command higher prices. Some of the minor crops, still considered exotics, like the mangosteen and the rambutan, have a more difficult postharvest life and therefore are exported by air.

Many countries from virtually all the continents have designated specific areas for production of fruits destined purely for export. Those countries include India, Malaysia, Thailand, and China in Asia; the Philippines and Australia in Oceania; South Africa and Ivory Coast in Africa; Mexico, Brazil, the United States, Peru, Costa Rica, and Chile in North and South America; Spain in Europe; and Israel.

While banana, pineapple, and citrus have a long history of international trade, the avocado trade burst upon the scene in the 1970s. The mango did not become a well-known fruit (from a consumption point of view) until the 1990s, with Mexico as the leading exporter. The papaya and the litchi may still revolutionize trade.

Of particular relevance for the development of tropical and subtropical fruit trade is the World Trade Organization (WTO) agreement in Marrakech on 15 April 1994 following the conclusion of the Uruguayan round of General Agreement on Tariffs and Trade (GATT) talks. Basically these agreements established the principle of free trade not exposed to arbitrary market entrance taxes, and obligate signatory countries (in practice most of the world) to use only sanitary and phytosanitary quarantine measures based on solid scientific information, thus effectively halting the use of these measures as a loophole to arbitrarily restrict imports.

As in other commodities, an interesting market is developing for organically produced tropical and subtropical fruits, and organic pineapples and bananas are available in Western markets.

### International Forum on Tropical and Subtropical Fruits

Many organizations and horticultural societies at national and international levels are dedicated to particular tropical or subtropical fruits (or a closely related group). Their members include amateurs, growers, researchers and academics, handlers, traders, and consumers. By reason of both magnitude and global concern, some of these merit special mention.

The International Society of Horticultural Science (ISHS), headquartered in Louvain, Belgium, has established a Commission of Tropical and Subtropical Horti-

culture with working groups in specific tropical and subtropical fruits. The ISHS meets regularly in different countries to discuss aspects of production, research, and trade of these fruits, and it holds an international congress every four years, which congregates a minimum of four thousand people.

The Interamerican Society of Tropical Horticulture was formerly known as the Tropical Region of the American Society of Horticultural Science. It holds annual meetings in different American countries with tropical crops to discuss the same issues mentioned above but including vegetables and ornamental plants.

The Intergovernmental Group on Bananas and on Tropical Fruits, under the auspices of the Food and Agriculture Organization of the United Nations (FAO), meets every two years to discuss issues related to marketing and trade.

**FRYING.** Fried foods, though widely considered delicate, are also among the most ephemeral. Regarding fried foods, a Chinese proverb states: It is better that your guests wait for their meal, than that the meal wait for the guests. Fried dishes cannot wait, and if allowed to stand, rising interior steam causes them to lose their crisp exterior and, thereby, their character.

Frying is a means of heat transfer that works by both conduction (direct contact) and convection (the natural movement of molecules in a fluid). Like broiling, boiling, and baking, frying is a method of cooking, but unlike water-based cooking (boiling, braising, or steaming), frying uses dry heat. Oil wicks moisture away from food surfaces. Because oil heats to a higher temperature than water, frying is faster than boiling, and fried surfaces, rather than becoming soft as they do when boiled,

broiled, or steamed, coagulate. The resulting fried food is incomparably tasty, crisp, and beautiful. Frying comprises not only deep-frying and pan-frying, but also the cooking method used to prepare common foods such as pancakes and fried eggs as well as less-known foods such as the Indian dish *dalia uppma*, an herbed bulgur with fried vegetables. Most, but not all, of the world's cultures have practiced frying.

Some fried foods are so popular that they can be identified as cultural stereotypes. American french fries and Middle Eastern falafel (chickpea or fava bean fritters) are examples. Native Americans of the Southwest are known for fry bread, and corn dogs are associated with New York's Coney Island. The American South has southern fried chicken, while in Asia, sweet potatoes are fried and served from vendors' carts. In Mexico, on the *zócalo* (the central square), vendors working from carts sell *churros*, a deep-fried pastry.

### Advantages and Disadvantages

Through the ages, frying has remained popular because it adds an outside layer of flavor and crunch to soft foods, such as eggplant and okra. In addition, frying cooks and browns beautifully. It adds texture and yields the smooth and taste-imparting feel that comes only from various oils and fats.

On the negative side, the process of deep-fat frying is dangerous and requires special equipment and controlled environments. To avoid the overflow of hot oil from the pan, large temperature-controlled deep fryers are used, and these pans are filled only about one-third of their depth with oil. In addition, to maintain the desired high temperature, deep fryers are not filled with food, but rather, food is fried in small batches. Moist foods are not placed in hot oil because they cause boiling and popping, which can be dangerous. To avoid burns and fires protective gloves and clothing, long-handled utensils, as well as fire extinguishers and baking soda, are used. Unlike water, oil can catch on fire, and oil fires spread quickly. If a pan of oil catches fire, the pan is covered with a lid, doused with salt, or sprayed with a fire extinguisher. A stream of water is not effective in dousing an oil fire.

The use of oils and fats has also become a health concern. Those who support frying claim that with fast, clean frying, only a small amount of oil remains on the food, and certain oils and fats are healthier than others. Olive oil and canola oil, monounsaturated vegetable oils, are recommended for human consumption, while saturated oils, such as palm and coconut oil, or saturated fats, such as butter or lard, are not recommended. Canola oil is considered good for one's health because of its ratio of linoleic acid (an omega-6 fatty acid) to linolenic acid (an omega-3). A balance of omega-6s and omega-3s is an asset to health, with other oils often lacking the omega-3s. Canola oil offers the best balance for omega-3 and omega-6 fatty acids.

## Methods of Frying and Equipment

Frying methods include sautéing, stir-frying, pan-frying, and deep-fat frying. These styles of frying form a continuum based on the amount of oil used, with sautéing using the least oil and deep-fat frying using the most.

Each of the principal frying methods is associated with a particular pan. Pan-frying is practiced in stainless steel, aluminum, and heavy cast-iron skillets, all with sloping sides. To sauté, there exists a French *sauterne* or sauté pan, which is wide like a skillet, but has low and straight sides. Deep-frying occurs in the deep fryer or wok, with either a fry basket insert, the long-handled slotted skimmer, or, as in China, the spider (small basket) attached to a long bamboo handle. Deep-frying thermometers are used to help the cook maintain a constant temperature. Finally, when fried foods, such as bacon or potato chips, are removed from the oil, they are placed on drip racks or paper towels. Deep-fat fryers are available in many sizes, from large multigallon commercial vats to small personal fryers that hold two or three cups of oil.

Other frying pans, too, are associated with specific foods. In crêpe pans, thin pancakes are cooked in a style associated with classical French cooking. Round or oval omelet pans are used to fry omelets. Heavy cast-iron chicken fryers are deep pans that include nipped lids that allow moisture to drip back onto the frying chicken. Restaurant kitchens often fry eggs, pancakes, sausages, and sandwiches on large steel frying surfaces called griddles, but home cooks can purchase small, hand-held griddle pans for the same purpose.

With a wok, many foods are stir-fried in the style of several Asian traditions. Woks are available as self-contained electric units or as wide, deeply sloped circular pans that fit over a gas flame. They are often sold with lids so that foods can be steamed for part of the cooking time. Before vegetables, seafood, poultry, or meats are added to the stir-fry pan, a small amount of oil is heated to a high temperature. In China, where stir-frying is an ancient tradition as well as a modern art form, small pieces of food are placed in a large pan over intense heat, and they are stirred quickly as they cook.

## Oils and Fats

Frying fats may be solid or liquid. In selecting an oil or fat, the oil should be fresh and clean. Its flavor should not overpower the food being cooked, and monounsaturated vegetable oils have been recommended for presumed health reasons. Solid vegetable shortenings contain emulsifiers, which make them good for use in cakes, but poor for frying. The emulsifiers lower smoke points to about 370°F. Margarine and butter spreads are also not recommended for frying as they contain a variety of fats and even water.

Butter is a special case, as it adds much-valued flavor to many foods. Butter, however, until it is clarified, contains milk solids and burns at about 250°F. When the solids are removed by clarification, butter is an improved

medium for frying, and its smoke point rises to 375°F. In India, both solids and water are removed from butter, and the resulting ghee or *usli* ghee is used for pan- and deep-frying. Lard as well as chicken, duck, and goose fats are also used successfully for frying. They impart excellent flavor but prompt health concerns among some researchers.

The purest flavor and safest frying are achieved when oil and fats are used one time. If frying is continuous for long periods, the oil requires changing, as it begins to darken or deteriorate. If frying oil is too hot, it will burn or break down, and if too cold, or less than about 300°F, the food being fried will absorb too much oil and become greasy.

## Smoke Points

Frying is faster than boiling or steaming because oils get hotter than do water or steam. Smoke points, however, limit maximum possible frying temperatures. Oil is too hot when it reaches the smoke point, the temperature at which the oil starts to smoke, deteriorate, and burn. Too much heat causes gaseous fumes and chemically active, free fatty acids to negatively impact flavor. Maintaining the optimum temperature can be challenging, as each time oil is used, it picks up food particles, breaks down, and loses its ability to absorb heat. In addition, over-used or rancid oil smells and tastes bad.

Oils deteriorate by oxidation or contact with the air, and heat speeds this process. Thus, in storage and cooking, contact with air should be minimized. For deep-frying, a deep and narrow pan is better than a shallow, wide one because it allows for less air contact.

Suitable frying oils have high smoke points; the higher the smoke point, the faster the cooking. Depending on the oil, smoke points range from a low 250°F to a high 520°F. For example, while water boils at 212°F, the favored frying oils such as olive, peanut, and canola have smoke points ranging from 410°F to 437°F and are best heated to 365°F. This temperature cooks food quickly yet does not burn these oils.

## Cultural Differences

During the British colonial period, frying spread from Europe to the Americas and Africa. American colonists adapted frying with great frenzy, and in a *Harper's* magazine story of 1866, Americans were said to be eating, "Fried ham, fried eggs, fried liver, fried steak, fried fish, fried oysters, fried potatoes, and last, but not least, fried hash." These preparations, as well as doughnuts, pancakes, and fritters, were served "morning, noon, and night," according to the magazine contributor, who thought that Americans consumed too much fried food.

Due to a lack of either resources or technology, frying was absent from some ancient cultures. Early European scholars writing about the food among the original inhabitants of the New World could not believe that these cultures did not have oil and did not fry. Because these

cultures did not have use of rotary motion, they could not reduce their quantities of peanuts or other seeds to oil. While European cultures used round wheels, Native Americans ground maize and other grains with a to-and-fro motion. After Europeans arrived, some Native Americans found the unfamiliar cooking oils and fats repulsive. In modern Latin America, with some exceptions, such as street fair food, fried tortillas, and *pescado frito* (fried fish), frying is not among the significant methods of cooking.

Foods, especially meats, were fried during the first century C.E. in many cultures around the Mediterranean. In Rome the term “frying,” or *frigere*, had two meanings, first, the toasting of grains in a dry skillet, and second, cooking in oil. From the eighth to the fifteenth century, fats and frying played an essential role in Arab cooking. Sheep tail fat was a frying delicacy; books from this region and period tell how to extract, clarify, perfume, color, and store this fat, which was used to finish-fry boiled meats. During the same period, Andalusia, Maghreb, and Syria were known for their olive oil, which was exported to Iraq and Egypt. The modern practice of browning, or lightly searing, meats through frying before stewing is described in Arab literature, also from this period. The result of this practice is that outer surfaces are slightly burned, and this enhances the flavor of stews.

### Sautéing and Pan-frying

The first step in preparing an Indian curry is to heat a small amount of oil and then quickly sauté a variety of herbs and spices. Similarly, Chinese cooks pre-heat oil, often with garlic, before stir-frying. High heat releases flavor and aroma. Stew meats, for example, are often pan-fried to seal juices and develop surface flavor. In French and American kitchens, sautéing is used to quickly fry vegetables and other foods with little oil.

Pan-frying is the use of a shallow, slope-sided frying pan or skillet to cook in oil. Like deep-frying, it depends on conduction and convection. In pan-frying, a layer of oil has four functions: it lubricates the surface; increases contact between the food and the pan; reduces cooking time; and increases flavor and color.

When frying battered fish or chicken, the oil covers the pan but not the food, but when frying pancakes, the oil is but a thin film to keep the batter from sticking. Asian cooks fry rice with all kinds of meats, seafood, vegetables, and nuts. Chinese fried rice is pan-fried in a skillet with very little oil, perhaps one tablespoon per cup of rice. The challenge of pan-frying thick items such as chicken parts is to cook to the center without burning the surface. The Chinese have effectively solved this problem by slicing foods thin enough so the surface and interior cook in the same time.

### Deep-Fat Frying

With deep-fat frying, foods are submerged in hot oil. Because of the expense of the oil or because of the difficulty of this method, deep-frying is associated with celebra-

tions, festivals, and street carnivals. American street fair vendors commonly serve deep-fried corn dogs, elephant ears, and funnel cakes. Deep-fat frying, also called deep-frying, is popular for breads, like southern cornmeal hush puppies, as well as for battered food, such as seafood or vegetables. Some food categories such as tempura, croquettes, and fritters are always deep-fried.

In India, *poori* breads are deep-fried, while *paratha* breads of whole wheat, potato, pea, chickpea, and corn are both griddle- and shallow-fried. *Poori* bread is a puffed up whole-wheat bread, much like *chapati*, another Indian bread that rather than being deep-fried is fried or “baked” on a griddle.

While European and Western cooks deep-fry with a single frying, the Chinese deep-fry in stages. After being marinated, foods are then deep-fried at a low temperature, maybe 290°F, and later finish-fried at a high temperature, 365°F to 385°F. This staged cooking increases crispness and color.

Batters reduce surface moisture, and a dryer surface reduces initial boiling. In addition, batters add color, flavor, and texture to many deep-fat fried foods, with green tomatoes, eggplant, okra, and even ice cream being examples of foods that are battered before they are fried. A meunière is a thin, light breading, or flour dusting, often used on fish and popular in traditional French kitchens. But batters can also be thick, as in the case of double, triple, or breaded coatings used for fried fish and chicken.

In summary, frying is quite expensive, somewhat controversial, almost universal, and very pleasing. The quick removal of moisture from food surfaces through the wicking effect of hot oil is a cooking method that will remain popular in homes and restaurants and at public events.

**FUNCTIONAL FOODS.** The term “functional foods” refers to foods and their components that may provide a health benefit beyond basic nutrition. Functional foods do more than meet minimum daily nutrient requirements—they also can play a role in reducing the risk of disease and promoting good health. Biologically active components in functional foods impart health benefits or desirable physiological effects.

All foods have a function when consumed in proper balance as part of an overall healthy diet. Functional foods may include whole foods, such as fruits and vegetables, which represent the simplest example. Those foods that have been fortified, enriched, or enhanced with nutrients, phytochemicals, or botanicals, as well as dietary supplements, also fall within the realm of functional foods.

The functional attributes of many traditional foods are only now being discovered. Examples include phytoestrogens in soy foods and a variety of antioxidants in fruits and vegetables, such as lycopene in tomatoes. Still, new food products are being developed with beneficial components, with a focus on wellness and the reduced risk of chronic disease (i.e., foods and beverages containing pre- and probiotics to maintain gastrointestinal health, calcium-fortified beverages to maintain bone health, and dressings and spreads containing plant stanol and sterol esters, which may decrease the risk of heart disease).

### History

Over two thousand years ago Hippocrates said, “Let food be thy medicine.” Although the concept of functional foods is not entirely new, it has evolved considerably over the years. In the early 1900s food manufacturers in the United States began adding iodine to salt in an effort to prevent goiter, representing one of the first attempts at creating a functional food through fortification.

Other twentieth-century examples include vitamin A and D fortification of milk and niacin and folic acid fortification of grains. These early fortification examples, however, focused on reducing the risk of diseases of deficiency. In the latter part of the twentieth century, consumers began to focus on wellness and the reduction of chronic disease. Research now focuses frequently on the promotion of health through many lifestyle factors, including the consumption of an optimal diet. As of 2002, researchers have identified hundreds of food components with functional qualities, and they continue to make new discoveries surrounding the complex benefits of phytochemicals in foods.

### Demand

Consumer interest in the relationship between diet and health has increased the demand for information on functional foods. Rapid advances in science and technology, increasing health-care costs, changes in food laws affecting label and product claims, an aging population, and a rising interest in attaining wellness through diet are

### WHAT IS THE RELATIONSHIP BETWEEN FOOD BIOTECHNOLOGY AND FUNCTIONAL FOODS?

Although many of the nutritional compounds in functional foods are either naturally present or added during processing, some may be the result of agricultural breeding techniques, including conventional crossbreeding and, in the future, food biotechnology.

Crossbreeding to produce a plant for a specific genetic trait, such as higher sulforaphane-containing broccoli, can take as long as a decade or more. Modern biotechnology, however, makes it possible to select a specific genetic trait from any plant and move it into the genetic code of another plant in a much shorter time span, and with more precision than crossbreeding allows.

Researchers are working with farmers around the world to develop dozens of functional foods through the use of this promising technology. For example, a high-oleic acid soybean oil has been developed through biotechnology to have the health benefits of soybeans (possible protection against heart disease) without the saturated fat content of other cooking oils. Other research holds promise for boosting levels of beneficial components such as carotenoids in fruits and vegetables.

among the factors fueling U.S. interest in functional foods. Credible scientific research indicates many potential health benefits from food components. These benefits could expand the health claims now permitted by the U.S. Food and Drug Administration (FDA).

### Consumer Attitudes

The International Food Information Council (IFIC) has been researching awareness of, and attitudes about, functional foods, through both qualitative and quantitative research. In 2002 telephone surveys with U.S. consumers were conducted, building on quantitative data collected in 1998 and 2000.

As in 1998 and 2000, the vast majority of consumers believe that they have a “great amount” of control over their own health. Also, in comparing the effects of nutrition, exercise, and family health history on health, consumers believe that nutrition plays the greatest role (71 percent versus 63 percent and 41 percent, respectively). Therefore, it is no surprise that 93 percent of Americans believe that some foods have health benefits that go beyond basic nutrition and that 85 percent are interested

**TABLE 1**

<b>Examples of functional components*</b>		
<b>Class/Components</b>	<b>Source*</b>	<b>Potential benefit</b>
Carotenoids		
Alpha-carotene	carrots	Neutralizes free radicals that may cause damage to cells
Beta-carotene	various fruits, vegetables	Neutralizes free radicals
Lutein	green vegetables	Contributes to maintenance of vision
Lycopene	tomatoes and tomato products (ketchup, sauces, etc.)	May reduce risk of prostate cancer
Zeaxanthin	eggs, citrus, corn	Contributes to maintenance of vision
Collagen Hydrolysate		
Collagen Hydrolysate	gelatin	May help alleviate some symptoms associated with osteoarthritis
Dietary Fiber		
Insoluble fiber	wheat bran	May reduce risk of breast and/or colon cancer
Beta glucan**	oats	Reduces risk of cardiovascular disease (CVD)
Soluble fiber**	psyllium	Reduces risk of CVD
Whole grains**	cereal grains	Reduce risk of CVD
Fatty Acids		
Omega-3 fatty acids, DHA/EPA	tuna; fish and marine oils	May reduce risk of CVD and improve mental, visual functions
Conjugated linoleic acid (CLA)	cheese, meat products	May improve body composition, may decrease risk of certain cancers
Flavonoids		
Anthocyanidins	fruits	Neutralize free radicals, may reduce risk of cancer
Catechins	tea	Neutralize free radicals, may reduce risk of cancer
Flavanones	citrus	Neutralize free radicals, may reduce risk of cancer
Flavones	fruits/vegetables	Neutralize free radicals, may reduce risk of cancer
Glucosinolates, Indoles, Isothiocyanates		
Sulphoraphane	cruciferous vegetables (broccoli, kale), horseradish	Neutralizes free radicals, may reduce risk of cancer
Phenols		
Caffeic acid		
ferulic acid	fruits, vegetables, citrus	Antioxidantlike activities, may reduce risk of degenerative diseases like heart disease and eye disease
Plant Stanols/Sterols		
Stanol/stanol ester**	corn, soy, wheat, wood oils	May reduce the risk of coronary heart disease (CHD) by lowering blood cholesterol levels
Prebiotic/Probiotics		
Fructo-oligosaccharides (FOS)	Jerusalem artichokes, shallots, onion powder	May improve gastrointestinal health
Lactobacillus	yogurt, other dairy	May improve gastrointestinal health
Saponins		
Saponins	soybeans, soy foods, soy protein-containing foods	May lower LDL cholesterol, contains anticancer enzymes
Soy Protein		
Soy Protein**	soybeans and soy-based foods	1 ounce per day may reduce risk of heart disease
Phytoestrogens		
Isoflavones, daidzein, genistein	soybeans and soy-based foods	May reduce symptoms of menopause, such as hot flashes
Lignans	flax, rye, vegetables	May protect against heart disease and some cancers; lowers LDL cholesterol, total cholesterol, and triglycerides
Sulfides/Thiols		
Diallyl sulfide	onions, garlic, olives, leeks, scallions	Lowers LDL cholesterol, maintains healthy immune system
Allyl methyl trisulfide, dithiolthiones	cruciferous vegetables	Lowers LDL cholesterol, maintains healthy immune system
Tannins		
Proanthocyanidins	cranberries, cranberry products, cocoa, chocolate	May improve urinary tract health and reduce risk of CVD

\*Examples are not an all-inclusive list.

\*\* FDA-approved health claim established for component.

in learning more about such foods. These levels of interest have been consistently strong since 1998.

The top ten foods that consumers identify as having a health benefit beyond basic nutrition include broccoli (9 percent), fish or fish oil (9 percent), green, leafy vegetables (9 percent), oranges or orange juice (9 percent), carrots (8 percent), garlic (7 percent), fiber (6 percent), milk (6 percent), calcium (5 percent), oats/oat bran/oatmeal (6 percent), and tomatoes (6 percent). The top five foods have remained consistent for the past three surveys; they are associated with America's top health concerns. Cardiovascular disease factors, including heart disease/attack, high blood pressure, stroke, and high cholesterol, remain the primary collective concern of American consumers. Cancer continues to concern almost a third (30 percent) of all consumers. Other areas of worry include weight (17 percent), diabetes (17 percent), and nutrition/diet (12 percent).

Almost two-thirds (63 percent) of Americans say they are eating at least one food in order to receive a functional health benefit. Although not significantly different from the 2000 results (59 percent), this does represent a significant increase since 1998 (53 percent).

Finally, the terms "functional foods" and "nutraceuticals" are often used to describe foods that may have health benefits beyond basic nutrition. "Functional foods" is preferred over "nutraceuticals" two to one (62 percent versus 31 percent). In reality, all foods have some function even if it is mostly taste and enjoyment. In addition, health benefits can be reaped from an apple, yogurt, or a filet of salmon as much as from calcium-fortified fruit juice or a supplement.

### Scientific Criteria

Many academic, scientific, and regulatory organizations are considering ways to establish the scientific basis to support claims for functional components or the foods containing them. FDA regulates food products according to their intended use and the nature of claims made on the package. Three types of claims are allowed on food and dietary supplement labels: (1) structure and function claims describing effects on the normal function of the body; (2) disease risk-reduction (health) claims implying relationships between components in the diet and diseases or health conditions, as approved by FDA and supported by significant scientific agreement; and (3) content claims.

Whereas science can confirm broad connections between some foods or eating patterns and health benefits, it is still not known how all individual food components work and whether there are synergistic effects among compounds. For example, numerous studies suggest that the consumption of a diet rich in whole grains, fruits, and vegetables is associated with a decreased risk of prostate, bladder, esophageal, stomach, and other cancers. However, the interactions among various components in these

### HOW CAN MORE FUNCTIONAL FOODS BE ADDED TO THE DIET?

The most effective way to reap the health benefits from foods is to eat a balanced and varied diet, including whole grains, lean meats, low-fat dairy products, legumes, fruits and vegetables, as well as foods with added beneficial components. Watch labels and read articles for information about foods and health. Before deciding to make any major dietary changes, however, take the time to evaluate your personal health and speak to your health-care provider on ways to help reduce the risk of certain diseases. It is also important to remember that there is no magic bullet that can cure or prevent health concerns, even when eaten in abundance. The best advice is to choose foods wisely from each level of the food guide pyramid in order to incorporate many potentially beneficial components into the diet.

foods continue to be elucidated. The roles of vitamins, minerals, fiber, antioxidants, and other phytonutrients do not stand alone.

A large body of credible scientific research is needed to confirm the benefits of any particular food or component. Although scientific studies point to many functional components in foods that provide added health benefits, more research is needed to determine which components are responsible for the beneficial effects as well as how individual components interact. The scientific community is still in the early stages of understanding the potential for functional foods. For functional foods to deliver their potential public-health benefits, consumers must have a clear understanding of and a strong confidence level in the scientific criteria that are used to document health effects and claims.

Functional foods are an important part of wellness, which includes a balanced diet and physical activity. The good news with functional foods is that what one does eat may be more important for health than what one does not eat. Individuals should consume a wide variety of foods, including the examples listed in Table 1. These examples are not "magic bullets." The best advice is to include a variety of foods from each of the food groups, which would incorporate many potentially beneficial components.

**FUNGI.** Fungi—sing. fungus; from the Greek *sphongis* (sponge)—are nonphotosynthetic and thus must absorb nutrients from organic matter formed by other organisms. The great majority of fungi obtain their food from dead organic matter and hence are known as saprophytes; a relatively small percentage derive their food from other living organisms and are known as parasites. Fungi may be unicellular (yeasts) or multicellular (mushrooms) and their cell walls usually contain chitin or cellulose and  $\beta$ -glucan. They may produce sexually or asexually by means of spores that are roughly comparable with the seeds of higher plants.

The fungal kingdom offers enormous biodiversity with over seventy thousand known species and an estimated 1.5 million species. According to molecular evidence (16S-like ribosome RNA sequences), the fungi may have originated from protozoan ancestors before the kingdoms Animalia and Plantae split; there is strong evidence that Fungi are closer to Animalia than Plantae

(Hawksworth et al.). Fungi are associated with some of the earliest remains of land plants. Some scientists believe that lichens (a stable self-supporting association of a fungus and an alga) might be transmitters, the earliest colonizers of land.

Fungi have contributed to the shaping of humankind's welfare since the beginning of civilization. Fungi are recognized as both beneficial and harmful in their relationship to humans although this role is predominantly beneficial. They are responsible for a major portion of food deterioration in developing countries; however, the preservative effects of fermentation of foods and beverages with fungi are well-known benefits, including organic acids, alcohol, antibiotics, pigments, vitamins, growth regulators, immunomodulating agents, and enzymes. Finally, various types of edible mushrooms are consumed as an important part of human diets in many countries.

### Fungi and Food Processing

Fungi used in food processing have been an integral part of the human diet since the beginning of civilization. In such foods, fungi are the agents responsible for imparting special flavors, textures, odors, or consistencies to food products. Fungi such as *Aspergillus* spp., *Rhizopus* spp., *Penicillium* spp., *Neurospora* spp., *Cladosporium* spp., and *Mucor* spp., as well as yeasts and many others have long been used to process a number of food products from soybeans to peanuts, rice, gram, maize, cassava, taro, and cacao beans.

**Fungal enzymes.** Food formulation using enzymes derived from fungi has undergone a rebirth in recent years. Enzyme suppliers have improved their ability to supply single-activity enzymes that do not have undesirable side activities (see Table 1 for a list of commercial fungal enzymes and their uses). Enzyme products have found increasing application for improving product clarity and yield and in replacing costly physical processes such as heating.

**Cheese manufacture.** Two general types of cheese are made with fungi as the ripening agents. Roquefort cheese is an example of cheese that is ripened primarily by growth of fungi (*Penicillium roquefortii*) throughout the cheese mass. Brie cheese is an example of one type of soft cheese that is ripened by the growth of fungi (*Penicillium camemberti*) on the outside of the cheese mass. In both types of cheeses, the fungi grow and release protein and fat-degrading enzymes that soften and ripen the cheese. Roquefort cheese requires about two months to ripen while Brie cheese requires only about one month to ripen.

**Baker's yeast.** Leavening, a process whereby batter or dough is caused to rise via the production of gas, especially carbon dioxide, was first discovered in Egypt. Today, most of the bread, cakes, cookies, and the like consumed by the public are prepared from leavened bat-

TABLE 1

## List, source, and uses of enzymes derived from fungi for food manufacture

Enzyme	Source	Use
$\alpha$ -Amylase, amyloglucosidase	<i>Aspergillus niger</i> <i>A. oryzae</i> <i>Rhizopus</i> spp.	Hydrolysis of starch in production of beer, bread; manufacture of high-fructose syrups
$\alpha$ -Galactosidase	<i>Mortierella vinacea</i>	Hydrolysis of raffinose to sucrose and galactose during sugar refining
Catalase	<i>Aspergillus niger</i> <i>Penicillium vitale</i>	Remove excess hydrogen peroxide formed during cake baking or that may be added during pasteurization of milk and cheese
Cellulase	<i>Aspergillus niger</i> <i>Trichoderma viride</i>	Improve palatability of low-quality vegetables, accelerate drying of vegetables, alter texture of foods, increase flavor of commercial mushrooms
Hemicellulase	<i>Aspergillus niger</i> <i>Trichoderma viride</i>	Manufacture of instant coffee
Invertase	Yeasts <i>Aspergillus</i> spp.	Increases sweetness in confections; yields soft center in chocolate-covered candies
Lactase	<i>Aspergillus niger</i> <i>A. oryzae</i>	Hydrolysis of lactose in milk products, enabling their use by lactose-intolerant individuals; production of syrups for use as sweetening agents
Lipase	<i>Candida</i> spp. <i>Aspergillus</i> spp. <i>Mucor</i> spp. <i>Rhizopus</i> spp.	Used for flavor development in cheese, chocolate crumb, apple wine, and cooking fats; improved whipping properties of egg whites; fish processing
Naringinase	<i>Aspergillus niger</i>	Reduce bitter flavonone glycoside derivative found in some citrus products
Nuclease	<i>Penicillium</i> spp.	Flavor enhancers
Pectic Enzymes	<i>Aspergillus niger</i> <i>Penicillium notatum</i> <i>Botrytis cinerea</i>	Remove turbidity from fresh fruit juices; removal of pectins before concentrating juice; clarifying agent in wine
Protease	<i>Aspergillus</i> spp. <i>Mucor pusillus</i>	Meat tenderizer; remove bitter flavors, replace rennin in cheese manufacture, chill-proofing of beer; reduce elasticity of gluten proteins in bread
Rennet	<i>Mucor</i> spp.	Milk coagulation in cheese manufacture
Tannase	<i>Aspergillus niger</i>	Treat insoluble material that forms during manufacture of instant tea

ter or dough. Most cakes and cookies are leavened chemically (by using baking powder) while most bread is leavened by yeasts (such as *Saccharomyces cerevisiae*). Yeasts develop and reproduce by producing buds on mother cells that subsequently enlarge and produce more buds. During growth, carbohydrates in the dough are metabolized to carbon dioxide that is trapped in the dough in the form of bubbles. During the leavening process, alcohol may accumulate in the dough to as high as 0.5 percent. The alcohol is driven off during baking and helps give the bread a pleasant aroma.

### Edible Mushrooms

Mushrooms have a long history of human consumption. Traces of puffball fungi have been found in Stone Age settlements. Over 4,500 years ago in ancient Egypt only pharaohs were permitted to eat mushrooms, which they believed were “sons of the gods” sent down to earth on lightning bolts announced by claps of thunder. The legend that mushrooms may have originated from thunder and lightning also existed among people of other ethnic groups. In Roman folklore, some fungi were believed to spring from the ground in places struck by a thunderbolt. In the Hindu tradition, there was a god named Soma that manifested himself to the priests in the form of hallucinogenic fluids. Some scientists believe that Soma was the fly mushroom, *Amanita muscaria*. A similar legend

may have existed among the inhabitants of the highlands of Guatemala and Mexico, where even today the people refer to *A. muscaria* by a common name meaning thunderbolt (Lowy).

**Cultivated species.** The cultivation of edible mushrooms worldwide reached 6.16 million metric tons in 1997, up from 1.26 million tons in 1981 (Table 2; Chang). This represents a 12 percent annual increase. Six mushroom genera accounted for 87 percent of the total mushroom supply (Table 2). These were *Agaricus* (31.8%), *Lentinula* (25.4%), *Pleurotus* (14.2%), *Auricularia* (7.9%), *Flammulina* (4.6%), and *Volvariella* (3%). China produced 3.92 million tons of mushrooms in 1997, or 63.6 percent of the total world output. The major mushroom of commerce in China is *L. edodes*, which accounts for 35 percent of the total output for that country. China currently produces 88 percent of the total world production of *L. edodes*.

***Agaricus bisporus* (button mushroom).** The cultivation of the button mushroom originated in the Paris region in France. Melon growers in this region discovered how mushrooms could be grown and started cultivating them in 1650. By the mid 1700s it was discovered that *A. bisporus* could grow without light, and that very favorable conditions for growing mushrooms prevailed in subterranean tunnels and caves. As a result of this discovery,

TABLE 2

## World production of cultivated edible mushrooms in 1981, 1990, and 1997

Species	1981		1990		1997	
	Fresh Wt (x 1,000 t)	%	Fresh Wt (x 1,000 t)	%	Fresh Wt (x 1,000 t)	%
<i>Agaricus bisporus</i>	900.0	71.6	1,424.0	37.8	1,955.9	31.8
<i>Lentinula edodes</i>	180.0	14.3	393.0	10.4	1,564.4	25.4
<i>Pleurotus</i> spp.	35.0	2.8	900.0	23.9	875.6	14.2
<i>Auricularia</i> spp.	10.0	0.8	400.0	10.6	485.3	7.9
<i>Volvariella volvacea</i>	54.0	4.3	207.0	5.5	180.8	3.0

successful culture was undertaken inside the numerous caves that were excavated for building stones and for gypsum. The caves presented, from a climatic point of view, several advantages over the previous growing conditions in open air. Factors such as temperature and relative humidity were much more constant in caves compared with aboveground conditions.

From France, mushroom cultivation spread to other parts of the world. The business grew and soon spread to England and other countries. By 1825, the first mushroom crops were being produced in caves in Holland. In 1865, mushroom culture entered the United States via England and the first mushrooms were grown on a small scale on Long Island, New York; by 1870 the industry had begun to develop.

Detail view of ceps (*Boletus edulis*), one of the most highly prized of all culinary mushrooms. PHOTO ANDRÉ BARANOWSKI.

The button mushroom is produced commercially on a selective substrate prepared by composting mixtures of wheat straw, hay, corn cobs, horse manure, or combinations thereof. The finished compost should have a nitrogen (N) content of 2–2.5 percent, and to reach such a level, nitrogen-rich supplements must be added. Inorganic nitrogen supplements can be added but only to provide part of the necessary amount. Organic sources of nitrogen include oilseed meal, brewers' grain, malt sprouts, and poultry manure.

Once the compost has been prepared, it is seeded with mushroom spawn that is prepared from a mother culture maintained by a spawn laboratory. Spawn is prepared by inoculating a pure culture of the mushroom onto steam-sterilized grain, usually rye or millet. Approximately one liter (500 g) of spawn is used to seed 0.5 m<sup>2</sup> of production surface that is contained in trays or beds inside environment-controlled production houses. Spawn run (vegetative growth of the mycelium) lasts ten to fourteen days, then a layer of neutralized peat moss (casing) is placed on top of the colonized compost to stimulate production of mushrooms. Approximately ten to fourteen days after casing, mushrooms are ready for harvest.

***Lentinula edodes* (shiitake).** Production of shiitake worldwide increased more than sevenfold in the fourteen-year period from 1983 (207,000 t) to 1997 (1,573,000 t; Chang). Most of this increase occurred in China, where more than ten million part- and full-time farmers cultivate shiitake. Shiitake is widely consumed in China, yet one-third of production is exported. In 1997, China produced approximately 88 percent of the total world output (Chang). In the United States, production of shiitake is a relatively new enterprise, having begun only in the late 1970s. In 1990, the United States produced 1,123 tons of shiitake and by 1999 production

reached 3,941 tons, a 3.5-fold increase (USDA). This increase in production was due, in part, to increased production efficiency and to increasing consumer demand. Farmers have learned to provide the specialized management this crop requires, thereby reducing production costs. The amount of controlled-environment production surface devoted to growing shiitake on synthetic logs has increased 2.9 fold from 1990 to 1999 (74,200 m<sup>2</sup> to 212,400 m<sup>2</sup>, respectively).

Sawdust is the most popular basal ingredient used in synthetic formulations of substrate for producing shiitake in the United States, but other basal ingredients may include straw, corncobs, or both. Starch-based supplements (20–60 percent dry weight) such as wheat bran, rice bran, millet, rye, and maize may be added to the mix. These supplements serve as nutrients to provide a more optimal growth medium (Royse).

***Pleurotus* spp. (oyster mushroom).** Oyster mushroom production increased at a rapid rate worldwide during the 1980s and then decreased slightly during the 1990s (Table 2). From 1986 to 1997, oyster mushroom production increased from 169,000 tons to 917,000 tons (a 5.4-fold increase). China was responsible for most of the production increase. In the United States, production of oyster mushrooms was 1,647 tons in 2001, up 2 percent from the previous year (USDA).

In the United States, the primary ingredients used for *Pleurotus* spp. production are chopped wheat straw or cottonseed hulls or mixtures thereof. After completion of pasteurization (140°F [60°C] for one to two hours) the substrate is cooled and spawned with the desired strain. There are several species of oyster mushrooms cultivated, with various colors of fruiting body. In Japan, bottle production of oyster mushrooms is most common. Substrate is filled into bottles, sterilized, and inoculated with *Pleurotus* spawn. Upon completion of the spawn run, bottle lids are removed and mushrooms emerge from the surface of the substrate. After the mushrooms are harvested they are weighed and packaged for shipment to market.

***Auricularia* spp. (wood ear mushroom).** Total production of *Auricularia* spp. in 1997 exceeded 485,000 metric tons (fresh weight; Table 2). This value is an increase of 366,000 tons or fourfold over 1986 levels (Chang). *Auricularia* spp. production now represents about 8 percent of the total cultivated mushroom supply worldwide.

*Auricularia auricula* and *A. polytricha* commonly are produced on a synthetic medium consisting of sawdust, cottonseed hulls, bran, and other cereal grains or on natural logs of broadleaf trees. For synthetic medium production of Auricularias, the substrate may be composted for up to five days or used directly after mixing. The medium is filled into heat-resistant polypropylene bags and sterilized (substrate temperature 240°F [121°C]) for sixty minutes. After the substrate has cooled, it is inocu-

While the white truffles of Italy are best eaten raw, France's black truffles (*Tuber melanosporum*) are most flavorful when cooked. This French society of truffle devotees meets annually to herald the beginning of the truffle season. PHOTO ANDRÉ BARANOWSKI.

lated with either grain or sawdust spawn. Light intensity of more than 500 lux during the spawn run may result in premature formation of primordia. Temperature, light intensity, and relative humidity all interact to influence the nature and quality of the mushrooms.

***Flammulina velutipes* (enokitake).** Worldwide production of *F. velutipes* has increased from about 100,000 metric tons in 1986 to about 285,000 tons in 1997. Japan is the main producer of enokitake. In the United States, enokitake production has increased at an estimated rate of 25 percent or more per year for the last four years. However, only about 60 tons of enokitake were produced in the United States in 2001.

Production of most enokitake in Japan is based on synthetic substrate contained in polypropylene bottles. Substrates (primarily sawdust and rice bran; 4:1 ratio) are mechanically mixed and filled into heat-resistant bottles with a capacity of 800 to 1,000 ml. Sawdust primarily from *Cryptomeria japonica*, *Chamaecyparis obtusa*, or aged (nine to twelve months) *Pinus* spp. appears to offer the best yields. In the United States, a sterilized, bran-supplemented medium, consisting primarily of corncobs, serves as the primary medium. When the substrate is fully colonized, the original inoculum is removed mechanically from the surface of the substrate and the bottles may be placed upside down for a few days.

To further improve quality during fruiting, temperatures are lowered to 37° to 46°F (3 to 8°C) until harvest. As the mushrooms begin to elongate above the lip of the bottle, a plastic collar is placed around the neck and secured with a Velcro® strip. This collar serves to hold the mushrooms in place so that they are long and straight. When the mushrooms are thirteen to fourteen cm long, the collars are removed and the mushrooms are pulled as a bunch from the substrate. The mushrooms then are vacuum packed and placed into boxes for shipment to market.

***Grifola frondosa* (maitake).** Japan is the major producer and consumer of maitake. Commercial production of maitake in Japan began in 1981 (325 t) and by 1997 reached 32,000 tons (a 98-fold increase). Maitake is produced primarily in the Japanese provinces of Niigata, Nagano, Gunma, and Shizuoka. Other countries, such as the United States, began maitake production in the early 1990s. Maitake production in the United States in 2001 was estimated at about 84 tons.

Most maitake is marketed as food. However, maitake has been shown to have both antitumor and antiviral properties. Powdered fruit bodies are used in the production of many health foods such as maitake tea, whole powder, granules, drinks, and tablets. Maitake also is believed to lower blood pressure, reduce cholesterol, and reduce the symptoms of chronic fatigue syndrome.

Commercial production of most *G. frondosa* is on synthetic substrate contained in polypropylene bottles or bags. A common substrate used for production is hardwood sawdust supplemented with rice bran or wheat bran in a 5:1 ratio, respectively. Other formulas include hardwood sawdust (70 percent based on oven dry weight basis) supplemented with white millet (20 percent) and wheat bran (10 percent). Some growers may add soil to the mix to stimulate fruit body formation. For production in bags, the moistened substrate is filled into micro-filtered polypropylene bags and sterilized to kill unwanted competitive microorganisms. After cooling (sixteen to twenty hours), the substrate is inoculated and the bags are heat-sealed and shaken to uniformly distribute the spawn throughout the substrate. Spawn run lasts about thirty to fifty days depending on strain and substrate formulation.

***Volvariella volvacea* (straw mushroom).** Cultivation of *V. volvacea* is believed to have begun in China as early as 1822. In the 1930s, straw mushroom cultivation began in the Philippines, Malaysia, and other Southeast Asian countries. Production of the straw mushroom increased from 54,000 tons in 1981 to about 181,000 tons in 1997 (about 3 percent of the total mushroom supply).

Many agricultural by-products and waste materials have been used to produce the straw mushroom. These include paddy straw, water hyacinth, oil palm bunch, oil palm pericarp waste, banana leaves and sawdust, cotton waste, and sugarcane waste. *Volvariella* is well suited for

cultivation in the tropics because of its requirement for higher production temperatures. In addition, the mushroom can be grown on nonpasteurized substrate, which is more desirable for low-input agricultural practices.

In recent years, cotton wastes (discarded after sorting in textile mills) have become popular as substrates for straw mushroom production. Cotton waste gives higher and more stable biological efficiencies (30 to 45 percent), earlier fructification (four days after spawning) and harvesting (first nine days after spawning) than that obtained using straw as a substratum. Semi-industrialization of paddy straw cultivation on cotton wastes has occurred in Hong Kong, Taiwan, and Indonesia as a result of the introduction of this method.

**Wild mushrooms.** In many developing countries, the collection and sale of wild edible mushrooms has become an important source of income for many people in remote forested regions. Despite a relatively short growing season, wild mushrooms provide many families with 50 to 100 percent of their income. World trade in wild, edible mushrooms is estimated at more than \$7 billion annually (Arora). The global trade in matsutake (*Tricholoma matsutake*), the most expensive wild mushrooms after truffles, is estimated at \$3 to \$5 billion. Matsutake may sell for as much as \$200 apiece in Tokyo markets. The King Bolete (*Boletus edulis*; also known as porcini, cepe, borovik, etc.) is the most popular wild mushroom of Europe. These may be served fresh in some upscale restaurants. Dried boletes are famous for their concentrated flavor and choice aroma and are available year round from almost anywhere in the world. Other wild mushrooms available on world markets include chanterelles (*Cantharellus cibarius*), morels (*Morchella* spp.), hedgehog mushrooms (*Hydnum repandum*), lobster mushrooms (*Hypomyces lactifluorum*), candy caps (*Lactarius fragilis*), and cauliflower mushrooms (*Sparassis crispa*).

**WARNING:** Collecting and ingesting wild mushrooms without the presence of an expert to correctly identify specimens can be very dangerous and should be discouraged since there are several deadly mushrooms that look like edible wild ones.

### Mycotoxins

Mycotoxins are chemical compounds produced by fungi growing on organic substances such as corn, cottonseed, or peanuts that, when ingested, have some undesirable effect on humans or on an animal consuming them. Adverse effects can range from vomiting to weight loss, various types of tumors, and in some cases, death. Over one hundred toxic compounds produced by fungi have been identified, and about forty-five of these occur in grain crops. Some mycotoxins are rare in occurrence while others such as aflatoxin are common in some years. The seriousness of the mycotoxin problem varies with the year, the crop being grown, and the intended use of the crop product. Most mycotoxins affect the blood, kidneys, skin, or central nervous system, and some may cause cancer.

## MUSHROOM COLLECTORS

The consumption of wild mushrooms has a lengthy history, dating back well over two millennia and extending throughout the world. For over two hundred years, mushrooms have been a cultivated crop as well. Despite somewhat negative images of mushrooms in the popular imagination and despite the possibility of real danger in their consumption, they have long been valued for their culinary and psychedelic properties. In 300 B.C. Theophrastus recorded that mushrooms were valued as food and for trade. Pliny, Juvenal, Martial, and Cicero all considered mushrooms to be great delicacies, and the Roman emperor Claudius was allegedly poisoned by a plate of mushrooms. Mushrooms are also mentioned in the Hindu Rig Veda and were eaten on the Indian subcontinent. Mushrooms were probably consumed for food and for their psychedelic properties in Mesoamerica, Siberia, and Scandinavia. Some suggest that the biblical "manna from heaven" was a fungus. By the eighteenth-century reign of Louis XIV, mushrooms were cultivated in caves near Paris. During the nineteenth century mushrooming became a popular leisure pursuit in Europe and America, and by the end of the century mushroom societies were formed.

One estimate placed the number of mushroomers in the United States at thirty million in the early 1980s. A survey conducted at the same time found that 22 percent of Americans collect wild mushrooms, and 15 per-

cent consume mushrooms they find. In the nations of eastern, central, and southern Europe with stronger mushroom cultures, these figures would likely be higher. Mushroom societies are found in every region of the United States, as well as Canada and Europe. In the United States, mushroom societies were founded in Boston and Minneapolis in the late nineteenth century. The North American Mycological Association, covering the United States and Canada, has approximately 2,000 members. These clubs organize talks, dinners, sharing of advice, and forays to mushroom collecting sites.

Novices worry about the toxic qualities of wild mushrooms. Despite this, the number of mushroom fatalities, at least in the United States, is very low. In some years, there are no fatalities although illnesses or hospitalizations might occur as a result of the misidentification of mushrooms, the contamination of otherwise edible specimens, or allergic reactions. Among the edible wild mushrooms that are most widely collected in the United States and Europe are morels, chanterelles, puffballs, boletes, and coral mushrooms. While the collection of wild mushrooms has increased in the past decades, the hobby is limited, and the greatest growth in "wild mushrooms" is likely to occur when these foods become cultivated and therefore perceived as safe to consume.

Gary Alan Fine

The genera of fungi of greatest importance to humans with respect to natural poisoning outbreaks are *Aspergillus*, *Penicillium*, and *Fusarium*. The *Aspergillus flavus* group produces aflatoxins (at least eighteen types known) that are considered the most important from the viewpoint of a direct hazard to human health. *Aspergillus flavus* is a common fungus that is found in soil, air, and decaying plant residues. Infection by *A. flavus* and subsequent aflatoxin production can occur in the field, in transit, or in storage. Most reports indicate that infection occurs in the field, while aflatoxin production can occur whenever the product is exposed to favorable conditions, either in the field or in storage.

Control of aflatoxin includes prevention of fungal growth, removal of toxins, and inactivation of toxin. Most control efforts have been directed toward control of aflatoxins in peanuts and corn. Hand picking, electronic sorting, and air classification accomplish control of aflatoxin in processed peanut products. Removal of shriveled, rancid, or discolored kernels has proven the most practical way of limiting aflatoxin contamination in peanuts.

In areas of the country with cool weather and heavy rainfall, mushroom collecting is a full-time occupation. These brothers make a living collecting a variety of mushrooms in Oregon's coastal forests. © DAN LAMONT/CORBIS.

**FUSION CUISINE.** Fusion cuisine is the deliberate combination of elements from two or more spatially or temporally distinct cuisines. Transcending conventional geographical and historical boundaries, it is a unique form of cuisine particular to today's postmodern world. The precise origin of the term "fusion cuisine" is uncertain although "culinary globalization," "new world cuisine," "new American cuisine," and "new Australian cuisine," all other names for fusion cuisine, have their roots in the 1970s in the emergence in France of nouvelle cuisine, which combined elements of French and, primarily, Japanese cooking (Sokolov, 1992). As nouvelle cuisine spread to other nations, it combined with elements of the foods of the host country. As Adam Gopnik has observed, while the Enlightenment of new cooking took place in France, the Revolution occurred elsewhere. Indeed, fusion cuisine has emanated primarily from the United States and Australia, but has spread to other parts of the world as well. Fusion cuisine may have taken off in the United States and Australia, because of those countries' short history relative to the rest of the world, their unique immigration histories, their lack of a cuisine that is clearly recognized by other parts of the world, and, most importantly, their lack of a culinary tradition.

As fusion cuisine evolves, many more ethnic and regional cuisines beyond French are being combined to form new hybrids. Exemplars of fusion cuisine include Pacific Rim cooking predominant in Australia and New Zealand, and Norman Van Aken's New World Cuisine (combining Latin, Caribbean, Asian, and American elements) found in the United States. An example of a specific fusion dish that combines classic Chinese recipes with French techniques and Mexican ingredients is Susanna Foo's pan-seared sweetbreads with veal dumplings made with ancho chili and served with Sichuan pickled relish and crispy shallots.

Fusion cuisine is distinct from historical combinations of cuisines, such as those that occurred in the sixteenth century when foodstuffs from the New and Old worlds mixed. It is also different from Creole cooking, which combines elements of French, African, Acadian, and Native American cooking. Geographers have described the long history of foodstuffs crossing geographical borders and the ways in which food is socially constructed through various processes (Cook and Crang, 1996; Bell and Valentine, 1997). Earlier forms of cuisine that combined elements from different regions or ethnic groups were reactive, rather than proactive, as is today's fusion cuisine. These cuisines emerged slowly from the everyday cooking practices that occurred within individual households and local communities. In contrast, fusion cuisine has developed rapidly and has found its way into everyday kitchens and restaurants as a direct consequence of the concerted and conscious activities of cultural intermediaries in the form of professional cooks, celebrity chefs, and cookbook authors. Fusion cuisine is an innovative and experimental process that demands from its practitioners the constant creation or re-creation of elements into novel food forms.

The social and cultural conditions that have contributed to the development of fusion cuisine, as well as most forms of contemporary cuisines, include increasing processes of globalization, increasing cultural flows through media and travel, the rise of a consumer culture, the modern food system, the expansion of the cookbook industry, the increased prominence of chefs throughout the world, the growth of the food and restaurant industry, and a greater concern with healthy lifestyles. Images constantly bombard the world, increase consumer knowledge, and escalate demand. Further, advances in technology have made foodstuffs from around the world available to all at any time. Boundaries are eliminated through the Internet, television, and the convenience and affordability of travel. Further, as consumers become increasingly concerned with living healthier lifestyles, the idea of mixing the healthiest elements from a variety of cuisines becomes appealing. For example, steaming and grilling may replace frying as a method of cooking, while herbs and spices are used in place of butter. The combination of these cultural and economic elements increases the likelihood that many culinary forms and combinations will exist.

Described as a blend of flavors and ingredients from different cultures, of different presentation styles, even of different cooking techniques, fusion cuisine has become a popular modern metaphor for hotel cookery around the world. Whether East has met West (or vice versa) successfully has been an ongoing discussion among food critics. PHOTO BY ANDRÉ BARANOWSKI.

Fusion cuisine, like fusion music and religion, appeals to multiculturalism, diversity, and novelty; it is also quite easy to market. It is an expression of the contemporary world of images and actively promotes a blending and diversity of cultures. It is a global cuisine in the sense that its elements are representative of cultures from around the world. One of the most interesting developments associated with fusion cuisine is that no single culture, with the exception of the French, dominates. Fusion cuisine combines elements of what are traditionally referred to as ethnic or regional cuisines, and may provide an opportunity to mainstream various ethnic and regional cuisines as well as provide opportunities for immigrant and minority chefs. Additionally, because of the hegemony of French cooking that persists in the culinary world, combining elements of French cooking may elevate the status of various ethnic and regional cuisines in a way that might not be accomplished otherwise.

Fusion cuisine has been met with mixed reactions because it is characterized by its lack of rules, or perhaps more accurately, by the precept that the rules ought to change constantly. Fischler claimed that contemporary gastronomy might be better thought of as “gastro-anomy” increasingly characterized by its lack of normative structure. Critics argue that practitioners of fusion cuisine deconstruct French and other cuisines (which do have codified culinary traditions and are clearly understood as unique culinary languages), and reassemble them into “new culinary sentences” that are not grammatically correct. Another related and frequently echoed criticism of fusion cuisine is that it is a haphazard mixing of cultures that lacks a respect for tradition. Further, particular cuisines become more or less popular as part of the hybrid, depending upon what is “hot” at the moment and not necessarily upon what tastes good. Because of increasing processes of globalization and consumerism, it is unlikely that fusion cuisine is going away any time soon. There are limitless possible combinations yet to be created.

**GADGETS, KITCHEN.** *See* Kitchen Gadgets.

**GAME.** The importance of nondomesticated animals, or game, in the human diet is unclear. Some anthropologists have argued that the advent of hunting game with tools was the critical development in the evolution of humans, resulting in such cultural characteristics as male aggression, sophisticated tools, and the sexual division of labor. The role of game in the human diet can more clearly be understood in light of ecological, nutritional, evolutionary, and cross-cultural information.

Except in the high latitudes occupied by peoples such as the Inuit, plants are generally the most abundant food source. Game is rarer than plants due to the second law of thermodynamics: As one moves up the food chain from plants, to herbivores, to carnivores, one finds that there is less to eat at the higher levels because energy is lost at each step in the chain. Not only is game rarer than plant foods, it may also be more difficult to obtain. Plants may protect themselves with thorns or toxins, but they do not hide or run away as animals do. These two points suggest that people might always choose plants over game as food sources. However, due to a process called biological magnification, game provides more concentrated packages of nutrients than do plants. In addition, some plant foods are difficult to digest without processing. Hence, some anthropologists classify game as “high-quality” foods and plants as “low-quality” foods.

Human nutritional requirements and digestive physiology suggest that at least some game is required in the diet. With the exception of vitamin B<sub>12</sub>, humans can obtain all the nutrients they require from plant foods. Vitamin B<sub>12</sub> can only be found in animal products. Humans require only 2.4 micrograms of vitamin B<sub>12</sub> per day and can generally store sufficient amounts for up to twenty years, but a chronic lack of vitamin B<sub>12</sub> in the diet may cause pernicious anemia, fatigue, and damage to the nervous system, and in children compromise growth. The need for protein is often the basis of arguments that humans require meat in their diet. While for humans game is a good source of protein, the required amino acids may be obtained from a mix of plant foods. In some regions, such as the Arctic, there is relatively little plant life; thus,

humans there generally require game to meet their protein requirements. Although humans are clearly capable of digesting game, their gut has a long digestion time similar to that of apes, which are primarily folivorous (Milton, 2000). In addition, it is possible that too much game may compromise human health. Game is generally leaner than meat from domesticated animals, and too much lean meat increases a person's metabolic rate such that ingested energy is used entirely to digest the food eaten. Consequently, lean meat must be eaten with energy-rich foods such as fat or carbohydrates. Furthermore, high-protein consumption may exceed the liver's ability to metabolize amino acids.

Human nutritional requirements and digestive kinetics are a function of the evolutionary history of the species. Therefore, an understanding of game in the human diet requires a consideration of the diets of human ancestors. It should be borne in mind that the role of game in the diets of human ancestors may be overemphasized, because plant food remains are less likely to be preserved in the fossil record than animal food remains. In addition, any plant food remains that do exist may have been overlooked by early researchers working with the perception that hunting was paramount in the subsistence strategies of human ancestors.

Hominids in Africa 4 to 2.5 million years ago did not leave archaeological traces such as “kitchen middens” and stone tools. Consequently, little is known of their diets. In lieu of archaeological data, dietary inferences have been made on the basis of paleoecological reconstructions, craniodental morphology, dental wear, chimpanzee behavior, and stable isotope analyses of their remains. Paleoecological reconstructions, craniodental morphology, and dental wear suggest that these first hominids subsisted primarily on fleshy fruits and leaves. Using chimpanzees as models for the behaviors of the first hominids also leads to the conclusion that they had a diet that was primarily vegetarian with an occasional animal product. This agrees with a stable isotope analysis of the bones of a three-million-year-old *Australopithecus africanus* from South Africa that indicates this hominid ate fruits, leaves, large quantities of grasses and sedges or animals that ate these plants, or both (Sponheimer and Lee-Thorp, 1999). Interestingly, the researchers suggest that these hominids

may have been capable of procuring game prior to the development of stone tools.

The evidence of 2.5 million years ago in Tanzania's Olduvai Gorge points to both tool makers and the consumption of game. Animal bones with cut marks indicative of butchering found in association with these tools indicate that the hominids who lived there ate game. How these bones were obtained is a subject of debate, because cut marks on the bones are sometimes found overlying tooth marks of carnivores, suggesting scavenging by the hominids. Some researchers argue for hunting or for confrontational scavenging in which groups of people drove carnivores off still-fleshy animals. Others argue that these people practiced passive scavenging from carcasses that had already been largely consumed. While evidence that might resolve this debate is sparse, the simplicity of the Oldowan tools may favor more passive scavenging (Klein, 2000).

Around 1.8 million years ago *Homo erectus* appears in the fossil record with a greatly expanded brain and more refined tools. The expansion of the brain dramatically increased the energy requirements, as the brain uses energy as much as ten times faster than average body tissue. Hence, it has been argued that increased access to high-quality, readily digestible flesh and marrow may have been essential for brain enlargement. However, corms, tubers, and other subterranean plant foods might have provided equal or greater nutrition for effort, and most historically recorded African hunter-gatherers exploited them heavily (Klein, 2000). Moreover, while there are many animal bones associated with *H. erectus* sites, there are few cut marks on the bones and a lot of carnivore teeth marks, suggesting that the fossil assemblage may not be due to human activity but to people inhabiting the same water-side sites as those favored by other animals.

The use of fire renders game a more viable food, as heating makes the tissue more digestible. So archaeological evidence of fire might help determine the consumption of game. The earliest possible site for fire is Locality 1 in Zhoukoudien, China (600,000–400,000 years ago), but this has been disputed due to the lack of mineral ash in deposits. To date, the earliest undisputed sites are deposits from 200,000 years ago in African, West Asian, and European caves.

The origin of Neanderthals around 130,000 years ago brings clear evidence of hunting of game. This conclusion is reached on the basis of faunal remains associated with Neanderthal living sites, wear patterns on their tools, and the analysis of stable isotopes and trace elements in their skeletal remains. Stable isotope analysis has been used in particular to compare the diets of Neanderthals with subsequent *Homo sapiens*. Such an analysis of nine *H. sapiens* and five Neanderthals from the European mid-Upper Paleolithic (about 20,000–28,000 years ago) indicates that the Neanderthals had diets composed primarily of large terrestrial herbivores, whereas

*H. sapiens* had a broader diet with a heavy reliance on freshwater resources (Richards et al., 2001). M. P. Richards and colleagues conclude that this transition was made possible by refined technology that made it easier to capture freshwater game. Stable isotope analysis of *H. sapiens* skeletons from sites in Israel dating from 70,000 to 10,000 years before the present reveals an increase in plant foods in the diet 20,000 years ago (Schoeninger, 1982). The change, it is argued, was due to refined technology for processing plant foods.

### Hunter-Gatherers

While anatomically near-modern people were present in Africa by 130,000 years ago, not until around 10,000 years ago were plants and animals domesticated. This means that for at least 77 percent of the time the species has been in existence, humans have obtained food by hunting and gathering. Hence, many of behavioral propensities, dietary requirements, and biocultural responses to food likely evolved prior to the advent of agriculture (Bogin, 2001). Given this, ethnographic and archaeological data concerning the diets of hunter-gatherers help explain the role of game in human diets.

As with the paleoanthropological data, studies of hunter-gatherer diets are biased by the perception among early researchers that hunting was the most important subsistence strategy. An additional problem in describing the natural or ideal diet of hunter-gatherers is the tremendous variation documented for such diets (Jenike, 2001). Despite the cultural and geographic diversity of hunter-gatherers, spanning from the rainforests of central Africa to the Arctic tundra of Baffin Island, similarities exist across these groups (Bogin, 2001). First, foragers consume a diverse array of food items; 105 species of plants and 144 species of animals among the !Kung San of southern Africa's Kalahari Desert, 90 species of plants and animals among the Ache of Paraguay's tropical forest (Hill and Hurtado, 1989), and 10 species of plants and 33 species of animals among the Dogrib of subarctic Canada (Hayden, 1981). Second, gathered rather than hunted foods are the primary source of dietary energy for most foragers. Richard B. Lee (1968) reported that, among 58 foraging societies, the primary subsistence base was gathering for 29, fishing for 18, and hunting for 11. Of those who relied on fishing or hunting, almost all were north or south of the fortieth parallel, a region researchers believed was not occupied by Paleolithic foragers. A review of the data in 2000 for 229 hunter-gatherer groups concluded that animal protein and fat provided up to 45 to 65 percent of the energy consumed and that 73 percent of these groups acquired as much as 56 to 65 percent of the energy they consume from animal foods (Cordain et al., 2000). When greater than 35 percent of the energy is from animal foods, the extra is from aquatic game.

The importance of game in the diets of many hunter-gatherer groups is apparent in paleoecological recon-

structions as well. Tim Flannery (2001), for example, writes that 13,000 years ago in North America, a sparse human population drove much of the megafauna to extinction by hunting.

### Nonhuman Primates

Given humans' close evolutionary relationship with apes and monkeys, a final line of evidence to consider is the importance of game in the diets of nonhuman primates. In general, most nonhuman primates appear to eat little animal matter because of the difficulty of obtaining it and a gut poorly suited to the digestion of animal matter (Milton, 2000).

This is not to say that game does not form an important part of the diet of some nonhuman primates. For example, observations of chimpanzees in different African sites reveals that they hunt often (Mitwani et al., 2002). The vast majority of the game hunted and eaten is red colobus monkeys, hunted primarily by males four to ten times per month with a success rate greater than 50 percent. The hunts entail a high cost in both energy expended and risks taken. Once caught, the meat is selectively shared with members of the troop. Interestingly, the chimpanzees do not appear to hunt to meet a nutritional need, as they hunt primarily during the seasons when fruit is abundant. Rather, among chimpanzees, game may be a political tool used to increase one's genetic contribution to subsequent generations (Mitwani et al., 2002). By sharing the meat, the hunter builds alliances within the troop. These alliances enable a chimpanzee to establish and maintain a high rank that appears to confer mating and reproductive advantages.

Ecological factors suggest that if humans were to choose their diet on the basis of availability alone, they would choose one composed primarily of plant foods. But, given the concentration of nutrients found in game and the difficulty of digesting some plant foods, they would likely wish to complement the plant foods with game. Nutritional considerations indicate that at least some game is required in the diet.

### Conclusion

Paleoanthropological data reveal that human ancestors of 4 to 2.5 million years ago ate primarily plant foods and possibly some game. Only at 2.5 million years ago does definitive evidence of the consumption of animals, obtained via scavenging or possibly hunting, appear. The expansion of the brains of human ancestors 1.8 million years ago does not necessarily mean they increased their consumption of animal foods. Rather, they may have increased their energy intake via the consumption of energy-rich plants. The Neanderthals of 130,000 years ago were the first hominids for whom game was a staple of the diet. *H. sapiens* also consumed game, albeit a greater variety and less focused on megafauna. Data from hunter-gatherers indicate they consumed a wide variety of plants and animals and that, by and large, plant rather than an-

The fallow deer as depicted in Edward Topsell's *Historie of Fourefooted Beasts* (London, 1658). The fallow deer was one of the most prized game animals of the medieval hunt. ROUGHWOOD COLLECTION.

imal products provided the bulk of the calories consumed. Studies of nonhuman primates document that game is regularly consumed among some species. Although the nutritional implications of this behavior are not clear, it does appear to have cultural implications among chimpanzees, where meat is shared by males to enhance their reproductive potential. Each line of evidence considered here suggests that, beginning 2.5 million years ago, game formed part of the diet of human ancestors, and that plant foods have provided the bulk of human calories. In short, game was a part of the diets of early hominids and hunter-gatherers, but plants predominated in the diet. The evidence is insufficient to clearly evaluate the impact of this subsistence strategy on human behavior.

**GAMERITH, ANNI.** Anni Gamerith (1906–1990) was one of the most famous European food ethnologists, known for her fieldwork and her theoretical insights. Born in Austria and a teacher by profession, Gamerith received her doctorate late in life at the University of Graz. The same university later gave her an honorary professorship for her scientific achievements. Her theory about the structure of traditional cookery was put forward for the first time at the First International Symposium of Ethnological Food Research held at Lund, Sweden, in 1970. This immediately won her international recognition. She proposed that there was an interdependence between food, cooking utensils, and cooking processes on the one hand and the fireplace on the other.

In essence, the type of food produced by a culture was dependent on one of two basic technologies. In former times, before the so-called *Sparherd* (literally "fuel-frugal" kitchen range) was invented, kitchen fireplaces were designed either for an open fire (hearth) or for a cooking oven. The hearth with its open fire could be close to the floor (where the cook had to bend down) or as high as a table (where the cook could stand upright while cooking). The food was boiled in the hot water of an iron kettle (hanging over the fire) or fried in the hot fat of an iron three-legged pan (standing over the fire). The food prepared in this way included both meat, which was often boiled, and various kinds of pancakes, with the dough fried in different ways. During the whole process of preparing the food on the hearth, the cook could intervene at any time.

Preparing the food in the cooking oven was another matter. Here, the food was cooked in the superheated air of the oven. Once the food was placed in the oven, the oven door was shut, and the door stayed shut to avoid having the oven cool down. The pots and pans used in this case were ceramic and were placed in the oven through the small hole in front by special devices called "pot forks" (*Ofengabel*) or "pot forks with wheels" (*Ofenwagen*). The food systems connected with the hearth and the cooking oven as the two main places of food preparation were structurally different and, according to Gamerith, could be referred to as "hearth food" (*Herdkost*) and "cooking oven food" (*Ofenkost*). In former times a region was characterized by one category or the other.

Woodcut from the *Neu-vermehrtes künstliches Koch-Büchlein* [New, Improved Artful Manual of Cookery] published anonymously about 1650. While the cook turns a roast on a spit, sausages are being smoked above the fire. Leaning against the wall is a pot fork for moving hot cookpots on the hearth. COURTESY HANS WEISS. ROUGHWOOD COLLECTION.

This 1840s Austrian woodcut shows a newly installed cast-iron cooking range with a bake oven in the back. The iron pots on the stove have undergone a radical redesign to account for the new technology. COURTESY HANS WIESS. ROUGHWOOD COLLECTION.

The *Sparherd* or kitchen range changed the situation completely. The incentive for its invention was the necessity of saving wood (hence the name, German *sparen* meaning 'to save'). The kitchen range combined the two formerly separate principles of preparing food: the hot surface of this stove is equivalent to the open fire (allowing boiling or frying), while the baking oven corresponds to the cooking oven (where one could bake or braise). With this innovation, the two previously separate food systems could be combined, and the former differences between areas where one method or the other was dominant disappeared.

Gamerith had encountered these exclusive systems in her fieldwork and was finally successful in finding the theoretical explanation. She also found a classification for the many different kinds of gruel and concerned herself very early with old methods of processing cereals from the aspect of nutrition. She was involved to a great extent in the organization of the museum at Feldbach, Austria, with its special attention to rural material culture in general, including many objects that were relevant for ethnological food research. In the museum at Stainz, Austria—again due to Anni Gamerith—food plays an important role.

#### GARDENING AND KITCHEN GARDENS.

The purpose of the kitchen garden is to supply the household to which it belongs with culinary herbs, fruit, and vegetables. There are, however, different types of households, and likewise different kinds of kitchen gardens. This entry deals mostly with the walled kitchen gardens that were created in northern Europe, and in particular in Great Britain, during the eighteenth, nineteenth, and early twentieth centuries.

#### Types of Kitchen Garden

The earliest garden of any kind was surely one that supplied its owner with edible and, to a certain extent, medicinal or useful household plants. People created

An organic kitchen garden at the Centre for Alternative Technology, Machynlleth, Wales. © JULIE MEECH; ECOSCENE/CORBIS.

such gardens in prehistoric times and they are still made today, albeit on a small scale and with fewer medicinal or household plants.

A productive garden requires certain essential elements that are common to all: They are usually situated close to the homestead; they need fertile soil, a supply of water, shelter from the worst of the weather, and protection from thieving birds, beasts, and people. Kitchen gardens with these basic requirements can be found in rocky, compost-filled craters on tropical islands; on cold, windswept seaside beaches; on rooftops in the center of huge towns; on narrow strips of land beneath ancient city walls; on river islets; and on terraced mountainsides. Security is provided by low stone or mud walls, hedges of thorns or spiky cacti, wooden or reed palings, ditches or moats, old bedsteads, and wire netting. Water comes from nearby springs, streams, rivers, or pools. In spite of the ingenuity required to make them productive, the produce of these gardens is likely to be erratic, as they are dependent on the seasons both for clement weather and rain; for this reason, and also because they usually have no supporting structures such as glasshouses, work sheds, or storage rooms, these gardens must be termed “primitive.”

The country dweller’s cottage kitchen garden forms another category. Lying somewhere between the basic, or primitive, kitchen garden and the much larger, walled kitchen garden, the typical cottager’s garden forms the very surroundings of the cottage itself with flower beds, fruit trees, narrow paths, and small lawns as well as an open, cultivated vegetable patch. It might include a little

orchard, bee hives, a pigsty, and a poultry house. The whole would be surrounded by a stout hedge, fence, or low wall. Before the arrival of modern piped water on tap, water would have been supplied by a well or a pump. The amount of produce grown on the vegetable patch might be sufficient to provide the family with a surplus of staples for storing over the winter, but the area would not necessarily be big enough to grow vegetables in succession, and the owners might not be able to afford a glasshouse, heated or unheated, for out-of-season luxuries. It could though, be laid out in a decorative manner, with a mixture of flowers and vegetables, trained fruit trees, and topiaried hedges.

The decorative kitchen garden, one designed as much for beauty as utility, is a constantly recurring theme in kitchen gardening. In the early twentieth century, when the fashion for this kind of kitchen garden had a little revival, it was referred to by English-speaking gardeners as the *potager*, an affectation that simply means “kitchen garden” in French.

Although well suited to it, the *potager* style of gardening is not confined to the cottage garden; it can be carried out on a vast scale as, for example, in the gardens of the Château of Villandry on the Loire in France, and it was often seen in walled kitchen gardens, too. In spirit the *potager* is poetic, inspired by classical Roman works such as Virgil’s *Georgics* (see especially *Georgic* 4) and *Hortulus*, a poem on gardening written about 840 by the monk Walafrid Strabo. Renaissance gardens, too, with their vine- and jasmine-covered arbors, statues, urns, and fountains; clean sandy walks lined with clipped box, pinks,

or herbs; little pavilions or gazebos at each corner overlooking the countryside beyond; and juxtapositions of fruit, flowers, and vegetables within were as pleasant to look at, contemplate, and walk in as they were useful. The theme continues into the seventeenth and eighteenth centuries, with the gradual removal of the kitchen garden from close proximity to the house and the separation of the garden as a whole into various compartments. The essayist Sir William Temple in his *Epicurus* of 1685 describes this arrangement: “so as to be like one of the Rooms out of which you step into another.” By the end of the eighteenth century, kitchen gardens in many of the larger estates had been removed to a considerable distance from the house. George Carter in his catalogue for the exhibition of the work of the landscape designer Humphry Repton notes that Repton wished the walk toward the kitchen garden to be as ornamental as the kitchen garden itself (pp. 67–68). Once there, the visitor would find features similar to those described in sixteenth- and seventeenth-century manuals on gardening: gazebos, fruit trees trained over hoops to provide shady walks, and beds lined by flowers with the more ornamental kinds of vegetable on show, the commoner kinds concealed. In winter, the visitor could seek the warmth and beauty of the glasshouses.

The garden at Villandry is a Renaissance pastiche; it was created on a sixteenth-century site in the twentieth century, and is based on contemporary designs for *parterres* by Androuet de Cerceau—not that there is any evidence that de Cerceau used vegetables in this way. In practice, in many a modern *jardin potager*, the *parterre*-like layout of the beds, and the heights and colors of the plants therein are of more importance than the supply of food to the household. When the cropping of one cabbage can jeopardize the beauty of a whole row, this type of kitchen garden begins to look like a plaything.
